WATSON, B. A., A. M., M. D., Jersey City, N. J.
WEBER, M. J., M. D., Lower Providence, Pa.
WHITE, J. WILLIAM, M. D., Philadelphia.
WILSON, J. C., M. D., Philadelphia.

YOUNG, JAS. K., M. D., Philadelphia.

INDEX.

Abdomen, enlargement of, 433.
Abdominal operations and after-care, 408.
Abdominal section in parturition, conditions requiring, 744; after-treatment, 773; practical points, 796.
Abdominal operations sequalæ, 814.
Abortion—for vomiting of pregnancy, 117; habitual, 205; medical and social aspects of, 314.
Abscess—mammary in the virgin, 220; pelvic, 380; pelvic in man, 128; psoas, 61; tuberculosis, treatment of with hot water flushing, 277.
Acetanilid for chancre and chancroid, 402, 602, 792.
Adenitis, cervical, in children, 194.
Africa, kola-nut of, 390.
African arrow poison, 7.
Alabama, medical law of, 373.
Albumen and other proteids, test for, 565.
Albumin in urine, 471; test for, 364.
Albuminuria—caused by antipyrine, 757; in acute catarrhal enteritis, 488; in infantile disease, 728.
Agaricine in night-sweats, 637.
Alcohol and digestion, 566.
Alexander, H. A.—letter, 284.
Alkaloid, opium, new, 18.
American Academy of Medicine, 394.
American childhood from a medical standpoint, 664.
American Electro-therapeutic Association, 87.
Amicrobian fever following arterial obliteration, 680.
Amputation below the knee, 687.
Amyl nitrite—in chloroform poisoning, 549; a cure for hiccough, 396.
Anæsthetics, administration to children, 684; in midwifery, 520; relative value of, 71.
Anatomy, pathological of ecthyma, 116.
Anatomy at Oxford University 804.
Ancephalia, 222.
Anderson, M.—Purpura Hemorrhagica and metrorrhagia, 350.
Anders, J. M.—Clinical Lecture, 263, 459.
Angeiocholitis, jaundice from, 293.
Angina pectoris, 471; nature and treatment, 757.
Animals, diseases of in relationship to those of man, 318.
Ankle, fracture, 61.
Ano, fistula in, 94.
Anti-kidnapping league, 177.
Antipyretics—action of, 750; in childhood, 604; treatment in children, 559.
Antipyrin—causes albuminuria, 756; injections of, for hemeralopia, 280; in puerperal fever, 131, 226; test for pure, 565.
Antipyrin in tonic spasm of parturient uterus, 837.
Antisepsine, Radlauers, 753.
Antisepsis for chiropodists, 71.
Antiseptics—benzin, 285; chloroform as, 168; elixir, French, 330; medication, 241; poultice, 527; remedy, tannic acid as, 57.
Antrum of Highmore, suppuration of, 332.
Apomorphia, 115.
Appendicitis, 216, 352; surgical treatment of, 715.
Aristol—in diseases of the eye, 509; in venereal disease, 547.
Arkansas, medical legislation in, 260.
Army medical board, 345; medical department, 227.
Arrow poison, African, 7.
Artesian wells in Iowa, 221.
Arthritis, rheumatoid, 89, 99.
Artificial anus, 687.
Aspiration for the treatment of hernia, 371.
Association of American Anatomists, 259.
Association of American Physicians of Berlin, 373.
Asthma and emphysema, 265.
Ataxia, hyposulphite of sodium and silver in, 509.
Ataxia sign, an early, 513.
Atropine in diseases of the heart, 509.
Auscultatory percussion, value of in diagnosis, 665.

Bacilli of Malaria, 562; of syphilis, 564.
Bacteria—pathogenic, 131; 474; Dr. Klein on, 802.
Bacteria of influenza 840.
Bacteriology, 354.
Bagwell, J. F., M. D., letter, 790.
Baldy, J. M., 526.
Barr, A. D., was it relapsing fever, 37.
Bartholinian gland, cancer of, 221.
Beates, Henry—the expectant treatment of syphilitic infection, 498.
Beef-tea, 133.
Behrens, B. M.—Permanent opening of drumhead 186.
Belladonna and electricity, for tachycardia, 331.
Benedict, A. L.—Metric System, 266.
Benzin as antiseptic, 285.
Bergey, D. H.—Dysentary, 205.
Beri-beri, 306.
Berlin aquarium, 69.
Berlin, Association of American Physicians, 373.
Berlin letter, 69, 329.
Bermuda letter, 787.
Bertrand, J. H., Leprosy, 9.
Bigelow, H. R.—letter, 340.—Electricity in Pelvic Surgery, 592.
Bile pigment in urine, 168.
Biological laboratory, the Da Costa, 525.
Birds, malaria in, 28.
Blackwell, E. T., Malarial Fever with Liver Involvement, 35.
Blackwell, E. T.—Vomiting of pregnancy, 190.

Bladder—exfoliation in female, 18; extirpation of, 26.
Blennorrhagia, albuminuria in, 598.
Blennorrhagic rheumatism, mercury in, 593.
Bigelow, H. R.—Medical Electricity and Batteries, 453.
Blood alkalinity of under normal and pathological conditions 804.

Book Reviews:

Whipple, Farrington H.—Clinical Examination of of the Urine, 751.

Blood, alkalinity affected by large doses of sodic sulphate, 646.
Bone grafting, 145.
Booth, D. S.—Pelvis abscess in man, 128.
Boric acid in otorrhœa, 364.
Börner, Earnest—Clinical Lecture, 647.
Bougies, metallic, in gleet and sexual neurasthemia, 554.
Brain, bullet wounds in, 10.
Brain, sarcoma, 216.
Breech presentations, treatment, 836.
Bright's disease, 1; ætiology, 759: treatment of 597; following infantile purpura, 513.
Bromide of ethyl, 71.
Bromoform, poisoning by, 549.
Bromoform in whooping cough 839.
Bronchitis, 651; chronic, 613; produced by vapors of picric acid, 637.
Brown-Sequard fluid in tuberculosis, 175.
Brush, H. L.—Letter, 369.
Burial of so-called stillborn children, 482.
Burns, treatment of, 48.
Burr, Wm. H.—Hydrogen peroxide, 705.
Byers, H. F., hystero-epilepsy, 812.

Cadwallader, D. W., fibro-papilloma of the bladder, 734.
Caffeine for post-partum hæmorrhage, 430.
Caffeine, hyperkinetic action of, in large doses, 596.
Calculi, biliary, 291.
California, health legislation in, 464.
California, Southern as health resort, 136.
Calomel and salt, 392.
Calomel in kidney disease, 457.
Canaliculi, occlusion of, 375.
Cancer, of a poisonous nature, 553.
Cancer of breast treated by methyl-violet, 641.
Cancer of Bartholinian gland, 221.
Cancer of stomach, 11.
Cancer of uterus, 4.
Cancrum oris, 284.
Carbuncle, 151.—and diphtheria, caustic treatment of, 252.
Cardiac—affections, strychnine in, 637; hypertrophy and dilatation, 650.
Cary, C.—Report of Clinic, 99.
Carey, Wm. A.—Inadequate hospital facilities, etc., 704.
Caries of costal cartilage treated with methyl-violet, 733.
Carbolic acid, variations in caustic action, 831.
Carolina, health legislation in, 464.
Carpaine, 548.
Catarrhal dyspepsia, 459.
Cates, B. B., Currette in fistula in ano., 94.
Carcinoma—disappears with development of phthisis, 794; of the breast, 688.
Castor oil, 37.
Castration of women, sexual life after, 557.
Cataract, soft, 375.
Cement, insoluble, 453.
Cerebro-spinal meningitis, specimen, 609.
Cerna, David.—The therapeutic uses of Kava-Kava, 492.
Cervix, flexible wire stems for stenosis, 136.
Cetrarin, therapeutic value of, 706.
Cheese, new poison in, 565.
Cervical glands, scrofulous ulceration of, 527.
Chancre and chancroid, acetanilid for, 402, 602, 792.

Chapman, J. M. T.—Mechanical treatment of umbilical hernia.
Chest—cotton and collodian dressing for, 392; traumatism of, 577.
Chicago Medical Record 804.
Children—dyspepsia of, 46; medication for, 196; pleuritic effusion in, 176; tonsils of, 179; vaccination of, 388; burial of so-called stillborn, 482.
China, leprosy in, 73.
Chinese treatment of diptheria, 104.
Chiropodists, 71.
Chloralamide, 755.
Chloroform, 96; in typhoid fever, 636; as an antiseptic, 168; in tracheotomy, 307.
Chlorosis, its treatment, 513.
Cholera toxine, isolation of, 765.
Cholera, epidemic of in Europe and America from 1830 to 1890, 605.
Chloroform poisoning, amyl nitrite in, 549.
Chorea, 445; association of Sydenhams and rhythmical, 598.
Chylochle—in New Orleans, 318; parasitic, 317.
Chronic acid in epistaxis, 308.
Chronic alcoholism, strychnine in, 783.
Chronic phthisis, 739.
Cities, micro-organisms in, 117.
Cirrhosis of liver and nervous symptoms, 833.
Clarke, A. P., M. D., hernia, 776.
Club-foot, 270; operation for, 178.
Cobb, W. H. H., Supra-pubic Cystotomy, 7.
Cocaine, 18; injections, death from, 85; new reaction of, 646; poisoning, 635; in small-pox, 550, dangers of, 508.
Cocaine, actions on circulation, 830.
Cocoanut for tape worn, 177.
Cod-liver oil, disguise for, 118.
Cold abscesses, treatment of, 681.
Colds, common, 440.
Colic, hepatic, 42.
Collapse, stimulant in, 174.
Colombia, leprosy in, 198.
Coltman, R.—Clinical Lecture, 233.
Comedones, 430.
Concussion of brain and spinal cord to certain conditions, 614.
Congress of American Physicians and Surgeons, 399.
Constipation, voluntary, 764.
Consumption—and emphysema, 767; antifebrinization in, 117.
Contagious Diseases Act, 391.
Convulsions—depending upon rickets, 607; in children, treatment of, 521, 604.
Copaiba as an expectorant, 676; as diuretic, 280.
Copper coloring matter in tea, detection of, 646.
Cornea, phlyctenular ulceration, chlrorate of potassium in, 586.
Copyright bill, 144.
Corpuscles, white, in pneumonia, 16; white, in disease, 550.
Corrosive sublimate as a disinfectant, 685.
Coryza, 199.
Cotton and collodion dressing for chest, 392.
Country practice, 314.
Cranium, temporary resection of, 759.
Creasote, 308.
Creasote, emulsion of, 106.
Cremation and its safeguards, 277.
Crematory at Heidelburg 805.
Crico-thyroid joint, luxation of, 70.
Croonian lectures, 766.
Croup—322; etherization in, 723.
Curative effect of operations, 663.
Curiosity, laryngological, 118.
Curetting of uterus in puerpural fever, 633.
Curetting of the uterus 827.
Currier, J. M.—Medical colleges of Vermont, 237.
Curtis, F. C.—Vesicular eruption in scarlatina, 244.
Cystoma of jaw, 214.
Cyst, parovarian, 487.
Cystotomy, supra-pubic, 38.
Cystoscopy, 7, 215.

Da Costa, J. M., 54.
Davidson, W. T.—Letter, 368.
Dawson, B. F.—Foreign body in ear for nine years, 462.
Day, time of to operate, 514.
Delafield, Francis—clinical lecture, 490, 650.
Diabetes—pathogeny, 600; Jambul in, 754, teeth in, 398.
Diaceturia in infantile disease, 725.
Diarrhœa, arsenite of copper in, 792; infusion of roses for, 400.
Dietetic employment of fat, 397.
Dietetics of chronic nephritis, 343.
Digataline, new method of administering, 549.
Digitalis in pneumonia, 829.
Digestion, influence of exercise on, 457.
Digestive troubles of infants, 362.
Digitalis and strychnine as circulatory stimulants, 509.
Digitalis in pneumonia, 708.
Diller, T.—Care of chronic insane, 549.
Diplomas in Pennsylvania, endorsing, 256.
Diphtheria 13, 16, 104; caustic treatment of, 252; resorcin in, 233; and tetanus, immunity from, 76; statistics and treatment, 560; therapy, 769; treated with hydrogen peroxide, 756; treated with mercurial inunctions, 800.
Dirtiest city in the world, 261.
Disease, and starvation, 344.
Diseases, names of, 333.
Disinfection, hints on, 564.
Diuretic, copaiba balsam as, 280.
Diuretine, alterability of 106; therapeutic effects, 678.
Dixon, S. G., Koch reagent for tuberculosis, 69; pharmacists, women, 65.
Dyspepsia, diagnosis and treatment of catarrhal, 459.
Dock, G.—Fevers of the South, 92.
Dodge, C. L.—Membranous croup, 322.
Doses, small, 104.
Druggists and venereal patients, 364.
Druggist's error in Germany, 398.
Drugs, impure, 289.
Drumhead, opening of, 186.
Dysentery, 209.
Dysmenorrhœa, dilation for, 54.
Dyspepsia, 235; of children, 46.

Eagleton, S. Potts—Hydrogen Peroxide, 542.
Ear, dangers of syringing, 304.
Ear diseases—new remedies for, 279; foreign body in for nine years, 462; suppuration of middle in infancy, 347.
Echinococcus of the lung, 550.
Eclampsia, post-partum, treatment, 723; treatment of, 558.
Ecthyma, 116.
EDITORIALS:
Abortive treatment of syphilis, 366.
American Medical Association, 79.
Amylene hydrate and epilepsy, 394.
Anæmia, treatment of, 338.

Appendicitis, excision of vermiform appendix in, 450.
Asthma in children, treatment of, 339.
Atlanta Medical and Surgical Journal, 201.
Barking cough of puberty, 139.
Boric acid in treatment of chronic constipation, 474.
Cancer germ, 78.
Chancres, excision of, 423.
Chronic constipation with boric acid, treatment of, 474.
Clinical lectures, 173.
Cocaine, dangers of, 508.
Concealed advertisements in medical journals, 309.
Curetting of the uterus in puerperal fever, 633;
Constipation, habitual, 671.
Da Costa, resignation of, 476.
Deaf infants, training school for, 475.
Deaths in cold weather, 283.
Digestion for abscess cavities, 311.
Diseases of women, electricity for, 449.
Dust and tubercle bacilli, 283.
Editor, farewell of, 476. (Dr. Dulles.)
Education and Diseases of School Children, 19.
Electricity for diseases of women, 449.
Electricity in treatment of extra-uterine pregnancy, 366.
Epilepsy and amylene hydrate, 394.
Farewell of the Editor, 476. (Dr. Dulles.)
Female pelvic organs, exploratory puncture of, 200.
Filaria sanguinis hominis, 310.
Genito-urinary apparatus, neuroses of, 223.
Gonococcus in diagnosis of vulvitis, 109.
Gynecological suggestions, 253.
Hematuria in typhoid fever, 281.
Herpes vacciniforme of infants, 452.
Homœopaths and Medical Examiners' Bill, 255.
Immigration and Public Health, 47.
Impressions, maternal, 282.
Incorporation of Pa. State Medical Society, 48.
Inebriates, legal restraint of, 138.
Infantile Malaria, 749.
Infants, herpes vacciniforme of, 452.
Intra-uterine stem pessary, 703.
Jefferson Medical College, 20.
Koch's fluid in non-tuberculous persons, 337.
Koch's method, 169.
Koch's remedy, 170.
Koch remedy for tuberculosis, 77.
Koch treatment, present states of, 641.
Legal restraint of inebriates, 138.
Lupus, nature of, 254.
Malaria, micro-organism of, 170.
Maternal impressions, 282.
Medical and Surgical College of New Jersey, 395.
Medical and Surgical Reporter, 507.
Medical examiners and medical education, 137.
Medical Examiners' Bill, 48, 255.
Michigan, University of, 452.
Micro-organism of malaria, 170.
Myxœdema relieved by grafting with thyroid, 108.
Nashville Journal of Medicine, 225.
Neuroses of genito-urinary apparatus, 223.
Neuroses, traumatic, 423.
Oesophagus, varices of, 199.
Pathogenesis of tetanus, 421.
Pelvic inflammation and general practitioner, 393.
Pelvic organs, exploratory puncture of, 200.
Pennsylvania, Medical Examiners' Bill for, 48.
Pennsylvania State Medical Society, 48.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (Absolutely Harmless.)

Is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT, AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. E. R. Squibb, of Brooklyn, writes as follows in an article headed "On the Medical Uses of Hydrogen Peroxide (*Gaillard's Medical Journal*, March, 1889, p. 267), read before the Kings County Medical Association, February 5, 1889:

"Throughout the discussion upon diphtheria very little has been said of the use of the Peroxide of Hydrogen, or hydrogen dioxide; yet it is perhaps the most powerful of all disinfectants and antiseptics, acting both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. The few physicians who have used it in such diseases as diphtheria, scarlatina, small-pox, and upon all diseased surfaces, whether of skin or mucous membrane, have uniformly spoken well of it so far as this writer knows, and perhaps the reason why it is not more used is that it is so little known and its nature and action so little understood. . . . Now, if diphtheria be at first a local disease, and be auto-infectious; that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and a sufficiently repeated contact. . . . A child's nostrils, pharynx and mouth may be flooded every two or three hours, or oftener, from a proper spray apparatus with a two volume solution without force, and with very little discomfort; and any solution which finds its way into the larynx or stomach is beneficial rather than harmful, and thus the effect of corrosive sublimate is obtained without its risks or dangers. . . ."

Further on Dr. Squibb mentions that CHARLES MARCHAND is one of the oldest and best makers of Peroxide of Hydrogen, and one who supplies it to all parts of the country.

CAUTION.—By specifying in your prescriptions "Ch. Marchand's Peroxide of Hydrogen (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of both CH. MARCHAND'S PEROXIDE OF HYDROGEN (Medicinal) and GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

Maltine

WITH

COD LIVER OIL

A combination of the best Norwegian Cod Liver Oil with MALTINE, in which, by the vacuum process, rancidity is prevented and disagreeable odor and taste of the oil removed.

BASE A POWERFUL RECONSTRUCTIVE

CONTAINS NO INERT EMULSIFIER

Does not disturb Digestion nor offend the Palate

A complete list of the Maltine Preparations and their formulæ will be sent on application.

(Please mention this Journal.) **THE MALTINE MANUFACTURING CO., New York, N. Y.**

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

Clinical Lectures.

ACUTE BRIGHT'S DISEASE.—TRAUMATIC PLEURISY.—TYPHOID FEVER.—DANGER OF MOVING TYPHOID PATIENTS.

BY MORRIS LONGSTRETH, M. D.,

PHYSICIAN TO PENNA. HOSPITAL.

Acute Bright's Disease.

Gentlemen: The small patient before us, a colored boy, apparently about 10 years old, was brought in by the patrol a few days ago. He had been picked up in the streets in an unconscious condition. It is said that for several hours previous to this he had lain unconscious, and had had several convulsions. On examination on admittance, he was still unconscious. His respirations were irregular and shallow, averaging about eight to the minute; his pulse was 130. The heart's impulse was forcible, as felt over the præcordia. His pupils were moderately dilated, the eyes being turned to the right, but there was no strabismus. He rapidly became conscious, and after two hours was able to talk. All that he complained of was pain in the abdomen; he had been at work on the morning of his attack, running errands. On examination of his urine, it not merely showed the presence of albumin, but also it was found on heating it that it became almost solid; only a little liquid remaining entangled in the coagulum. Delirium followed during the next day and night. The temperature on admission was 97°; on that night it rose to 100°; but since it has fallen gradually to normal except on the third day following another convulsion. On listening to his heart beat, a soft systolic murmur was heard, caused undoubtedly by the rapid action of the heart. There was no evidence of disease elsewhere. At first the boy was given tincture of digitalis, ten drops every four hours, and with this benzoic acid every third hour. As soon as he was able to swallow, he was given a compound jalap powder, a drachm in divided doses, which was followed on the following day by free movement of the bowels. There was still pain in the abdomen, the nature of which it was impossible to determine on account of the condition and age of the patient; but it was not increased by the medicine. On the second day after admission, only two ounces of urine was passed. The next night another convulsion appeared. The boy was unconscious also again on the next day; this was followed by delirium. In the afternoon and evening only four ounces of urine were passed. That night he was given a hot-air bath and a sixth of a grain of the muriate of pilocarpin hypodermically. This was not followed by any great amount of perspiration, although a slight amount of moisture was detected on the skin. Apparently these measures produced no relief of the symptoms; but on the following day the boy felt more comfortable, and passed more urine—12 ounces in the day. His urine is still heavy with albumin; it contains epithelial and granular casts; but it has greatly improved in character. He is now sleeping well, and taking nourishment; his tongue is clearing, he has still some pain in the abdomen, but no delirium or convulsions. From noon yesterday until this morning he has passed 21 ounces of urine; it contains some *débris* and thick purulent-like material, consisting nearly entirely of epithelial cells and casts.

There are several ways for testing for albumin in cases where it is due to inflammatory cause. The acid can be put below in the test tube, with the urine on top; or the urine can be placed in the test tube and the acid rolled below or placed below with a pipette. By this last means of procedure a wider band of albumin can be obtained from the same case than where the urine is

simply poured on top. Another excellent method for the same purpose is to fill the test tube half full of urine and boil the upper half by tipping the tube over an alcohol flame. In this way you will undoubtedly break many test tubes, especially if the flame is in a draught; but it forms a very delicate mode of comparison, the urine in the lower part of the tube remaining unchanged. This method I believe to be the best for detecting small amounts of albumin caused by inflammatory changes. Many other methods, of course, may detect albumin when present in far smaller amounts than does this boiling test; but for daily practical work I wish to enforce the statement I have made.

As to the origin of this boy's illness we are unable to speak positively. We have an indefinite history of a wetting some time ago; but its date and extent are not known. He represents excellently well an attack of acute Bright's in a child. He is restless yet and requires constant watching. The doses of benzoic acid and digitalis will be gradually reduced as the kidneys increase their action; if thorough relief does not appear later in his attack we will resort to hot-air baths again.

Traumatic Pleurisy.

Our next patient is also a colored boy, 14 years old. He was admitted on November 6, with the following history. Eight days before, while playing with some other boys, they placed a rope around his chest, and, throwing its end over a beam, dragged him up in the air a number of times. This produced no pain until four days later, when he experienced a sharp, severe, stabbing pain in the right side, well up under the axilla. On attempting full inspiration, this pain was greatly increased; and since its commencement it has been growing rapidly worse. His temperature, on admission was $104\frac{3}{5}°$, and he lay in bed on his right side, which position gave him some relief. The expression of his face showed that he was suffering intense pain. His respirations, which were short and shallow, ran 36 to the minute; his pulse was over 100. His high temperature was due to moving him into the hospital, and the pain thereby produced; it was too high, even for severe pleurisy in a boy of his age. At the point exactly where the rope had been placed around his chest, there was a marked friction sound. Nothing could be felt. The lower part of his chest gave a good respiratory note. On coughing, many râles could be heard in the lung. At first he had considerable expectoration; the sputa were rusty in color; but there was no blood in clots.

It is a common thing for traumatism to produce pneumonia as well as pleurisy, even when no injury has been done to the rib. The pneumonia is more common than pleurisy alone. The rusty sputa is generally the first sign obtained. In this case the effusion in the chest disguised, to a degree, the signs of the pneumonia; and in the conjoined diseases the one starting or developing first always predominates; the pleural effusion cannot become excessive simultaneously with a solidification of the lung with the pneumonic exudation. This boy coughs only on exertion now; the expectoration of rusty colored sputa has stopped.

The question now arises as to the course of treatment. It is evident that we cannot treat such a case as ordinary pneumonia or pleurisy, with an underlying constitutional or diathetic factor. These cases of traumatism must be kept as nearly as possible in the condition given to a broken bone. The chest movements must be restrained, just the same as in a fractured rib. In this case there has not seemed to be an urgent necessity for such strict treatment. We have given the boy anodynes—the acetate of morphia, $\frac{1}{16}$ of a grain every three hours—together with eight grains of the acetate of potash, to help absorb the fluid and favor its excretion.

I will present another case of pleurisy of similar origin, which shows a not infrequent result, following similar chest injuries. This man, 58 years old, was admitted on November 3. He experienced, in the Spring, a fracture of several ribs. This had not inconvenienced him since, until October, when he was exposed to excessive wet weather, remaining for long periods in wet clothes. There appeared then, a cough, shortness of breath, and a sharp pain through the seat of the former fracture. This is a very common history—the selection of the seat previously injured for the recurrence of a pleurisy. An examination of his chest reveals a few crackling râles at the base of the right lung; his heart and the other lung are normal. There is diminished resonance on the affected side below the nipple, and behind the axillary

line dulness is very marked. This dulness is not changed in area or position by change of posture; this is very likely to occur in these recurrent pleurisies, because the pleural sac is, in parts at least, adherent, and the new effusion is probably sacculated and limited in its amount and extent. There is no rusty sputa as we are likely to have in a fresh traumatic case. It is a free frank pleurisy, with some bronchial trouble. The temperature was higher than we would expect; this was due to the agitation experienced by transmission to the hospital and subsequent physical examination. In such a case, always wait to see if the temperature will drop down without the administration of any marked remedies; it frequently or generally does so. The treatment for this man is the same as in the other case; the acetate of potash being given in fifteen-grain doses and the acetate of morphia in one-third grain doses. In addition poultices, consisting chiefly of mustard, were applied to the chest. These were intended to relieve the pain. The little effusion which existed is going off. Adhesion is occurring at the lower part of the lung. A layer of lymph has been thrown out and is becoming adherent.

Another point, practical in its bearing, occurs to me here. Generally, when you see these cases, the bowels have not been acting for several days, and the question arises, Should you give a purgative? It is always my practice to try to avoid its administration, if possible. It is a painful strain to the patient little able to handle himself properly; so that, if possible, the purgation should be put off. The quiet and rest are more essential. Later not only are enemata of service, but the remedies which drain the intestinal mucous membrane are indicated.

Typhoid Fever.

The next man, 22 years old, was admitted November 1, with the diagnosis of typhoid fever. He is a printer, and was never ill before. A week prior to his admission, dizziness occurred, with headache, loss of appetite, malaise and aching in the joints and bones; and his bowels were very constipated. Two days before his admission he had an attack of nose-bleed. On examination some harsh breathing was noted under the right clavicle; there were no bronchial râles; the pulse was acting rapidly; and there was a slight systolic murmur at the apex. This murmur has since disappeared. His liver was normal in its area, but the spleen was slightly enlarged. His temperature was 99° on admission; and, on examination of his skin, four or five suspicious spots were seen over his abdomen. After pressure, these spots appeared with rekindled redness. The fresher ones came back promptly, the older ones more slowly. At present his abdomen is not distended, and there is a little gurgling in the right iliac fossa. Don't seek for this latter symptom. It is much better to do without it. You may easily punch through the thinned and ulcerated intestinal walls in searching for it; but if on touching the surface gently you get the symptom, so much the better. It shows the presence of air passing through fluid. Active manipulation of the abdomen at this point is not only dangerous to the patient, but, in liquefying solid matter and producing artificially gurgling, may be deceptive for diagnostic purposes. The tongue is swollen and coated; it shows a wedge-shaped clearing area. The pulse is not high; the respiration is even; and there is a tendency of the temperature to return to normal; in fact fourteen days from the day of first complaint it has become in the morning sub-normal. The spots which you see here, which have lasted for many days, are seen unusually late.

The treatment of this patient has been of the simplest character. Enemata, to prevent impaction—for his bowels have seldom moved—have been administered. He is taking dilute muriatic acid and quinine. He is being given a liquid diet, and the surface of his skin is regularly sponged.

In cases of typhoid fever, this has been the experience of the Pennsylvania Hospital: Brought into the hospital before the end of the first week, unless the cases are virulent, they are likely to terminate favorably. In the same grade of cases brought into the hospital in the second week of their disease, the mortality is increased threefold. When brought in in the third week, the mortality is terrific; it is a miracle if the patient does not die. The experience of London hospitals has been the same, especially at the London Fever Hospital. The practical lesson of this is to move your patients early. If mistaken in your diagnosis, no harm has been done; your patient can walk out of the hospital in a few days, if he does not show the existence of typhoid; but waiting until you are certain of your diagnosis, you

are increasing the risks to your patient tremendously if you intend to send him to a hospital. In a case which you have seen late in the course of the disease, no matter how uncomfortable it may be at home, no matter how poor the bed or room and wretched the nursing, remember the fatality consequent upon moving a patient.

CANCER OF THE UTERUS.

BY E. E. MONTGOMERY, M. D.,

PROFESSOR OF GYNECOLOGY, MEDICO-CHIRURGICAL COLLEGE; OBSTETRICIAN, PHILADELPHIA HOSPITAL.

Gentlemen: The first patient I bring before you is a German woman, fifty-four years old; her father, one sister and two brothers died of phthisis. She came to this country at the age of fifteen years; was married and has had eight children. Eight years ago she had syphilis. For the last two years she has been suffering with severe pain in the back, and occasional prolapse of the rectum. During the last two months her suffering has become greatly increased; the gravest symptom being periodical uterine hemorrhages, and recently, the discharge of feces through the vagina, indicating the development of a recto-vaginal fistula. The symptoms—pain, hemorrhage and fecal discharge from the vagina—are her most serious disorders. Upon examination, I find a thickening of the walls of the orifice of the vagina; and, as I proceed, I meet with ulceration on the posterior surface, from which an offensive discharge takes place when the parts are subjected to pressure. This thickening and ulceration extends from the vagina to the uterus; so that it is difficult to define one from the other; and an opening can be determined between the vagina and the rectum through which the feces pass. The disease has evidently developed in the uterus and extended from it to the vagina, involving more particularly the left lateral and posterior walls, although the anterior wall has not entirely escaped. As the disease primarily involved the uterus, we may have in addition a recto-uterine fistula.

I regret that it is so difficult to exhibit the lesions present in a case of this kind; but I shall take occasion to exhibit to you the *post-mortem* specimens removed from a woman who died in the institution two days ago. The woman was thirty-seven years of age, a German and a cook. She menstruated regularly, and had had two children. During the latter part of her life she suffered with severe pelvic pain, vaginal hemorrhage and profuse discharge. One year ago she began to experience severe pain at the menstrual period; later the menstrual flow was excessive; and within the last few months an inter-menstrual hemorrhage occurred, followed by a profuse offensive discharge. Her bowels were constipated, her urine was mixed with blood and for some months feces had passed through the vagina. At the autopsy the heart and lungs were found healthy; the pelvic viscera were matted together, and there was extensive involvement of the lymphatic glands in the pelvis; the right ureter was distended to the size of a finger, and, upon being broken, was found to be filled with pus. The pelvis of the right kidney was dilated and contained considerable pus; the left kidney and left ureter were normal. Upon examination of the vagina, it was found that the posterior surface was completely destroyed, forming a large opening into the rectum, through which the contents of the bowel passed; infiltration extended laterally quite extensively upon the right side of the vagina, and had undoubtedly given rise to obstruction of the right ureter, causing the accumulation of pus within the kidney and ureter, inducing at first a hydro-nephrosis, and later a pyo-nephrosis of the kidney. The uterus was found free from disease; which indicated that the vagina was the seat of its origin.

Cancer of the uterus is a very frequent disease. This organ is the seat of cancer in one-third of the cases of malignant disease in women. Primary cancer of the vagina is exceedingly rare. In the majority of cases the disease extends from the cervix to the vagina. When the disease originates in the vagina, it is usually of the ephithelial form and is more rapid in its progress; the walls of the adjoining viscera being thin, they are soon perforated, and the bladder or rectum opened. Where it is seen sufficiently early, the proper method of procedure would be the removal of the diseased part, even if it were necessary to open into the adjoining viscus to accomplish it, and to bring together the denuded surfaces with sutures. They are hopeless cases for treatment, as the disease, with few exceptions, soon recurs.

Cancer originating in the body of the uterus is also of rare occurrence, it occurs in

about two per cent. of the cases in which the uterus is the seat of the disease. It is quite evident why this should be true; the cervix is that portion of the uterus which is most likely to undergo injury during parturition, and the efforts on the part of nature to restore such lesions result in the formation of tissue of lower vitality, which, under favorable occasions, undergoes increased cell proliferation. While it is true that malignant disease may occur in women who have not borne children, it is rare, and it occurs with the greatest frequency in women who have borne a number of children, and who have undergone lesions of the cervix as a result. The disease may occur at any age, from twenty to seventy years. It takes place, however, with the greatest frequency at or near the climacteric. It may begin upon the mucous surface, in which the cell proliferation leads to the formation of large cauliflower growths, which may fill up the vagina. In these the vessels are much enlarged; their walls are thin and without muscular coat, so that they rupture easily; and as they have no contractile power, hemorrhage is a marked symptom of the disease. In other cases, the walls of the cervix become rapidly infiltrated, and are found to be hard and dense, giving rise to most excruciating pain. This form is known as that of scirrhus. Cancer of the uterus seems to progress with greater rapidity when it occurs in the young. It takes place in such cases where there has been a family predisposition to the development of tubercular trouble, so that it is quite possible that the peculiar condition of health, of the individual, favors the rapid progress of the disease.

The prominent symptoms of cancer of the uterus are pain, hemorrhage and offensive discharge. Of these, hemorrhage is usually the first, and may make its presence known by increased flow at the menstrual periods; later the hemorrhage may take place at irregular intervals, or give rise to a continuous bloody discharge. Frequently the patient suffers from a profuse, thin, watery discharge, which has somewhat the odor of decomposing flesh. Pain, while in many cases a marked symptom, is not a constant one, some patients, indeed, going through the whole course of the disease without suffering any distress. Pain, when felt, is usually in the region of the uterus, and radiating from it. As a result of the profuse bleeding, the constant discharge, and a severe sleep-destroying pain, the individual soon becomes emaciated, presenting a wearied look, often a straw-yellow color, producing what is known as cachexia. This condition is due, in a great degree, to the chronic poisoning of the system of the patient by the absorption of septic material, which takes place from the pockets of the decomposing tissue. That this has a marked influence in its development, is evident from the fact that those patients who undergo operation, by which this tissue is removed, temporarily regain their color and healthy appearance to such a degree as to lead their friends to hope that a mistake has been made as to the character of the disease.

Patients suffering with this disease appeal to our sympathy. There is no more distressing position to be placed in, than to be physician to a lovely woman, who is the victim of a disease that has progressed to such an extent as to render it ineradicable. It is very important, therefore, in every case presenting symptoms of a suspicious character, to proceed, at once, to a careful examination of the patient, and where she is evidently suffering from incipient development of malignant trouble, to resort to operative interference. It is now well recognized that cancer in the uterus, as in the mammary gland, is, in the beginning, a local disease; and if it is attacked before it has extended to the surrounding structure, we may hope to afford our patient immunity against its return. We have not, however, the same opportunity of following the disease when the uterus is its seat, as where it has involved the mammary gland.

In the latter organ, it is accepted as an established rule, that removal of the corresponding axillary glands should accompany the removal of the mammary gland; but we cannot carry out such a rule in operations upon the uterus. The cases in which we may hope to proceed to a radical operation where the uterus is the seat of the disease, are necessarily limited. It is only in those cases in which the disease is confined to the uterus, and in which there is no evidence of the involvement of the vagina or extension to the broad ligaments, that we may hope to be successful in extirpating the disease. Yet even in such cases, we cannot say when the disease may have extended from this organ, through the lymphatics, to the glands of the pelvis; and when this is the case, a return of the disease is certain to take place.

Now, two plans of procedure are advocated for this—high amputation of the cervix, and entire removal of the uterus. I am aware that in making this statement, I do not name amputation by the ecraseur, by the galvanic ecraseur, by the scissors or by the knife; such operations hardly deserve the name of being palliative, as it is very rarely that they succeed in arresting the progress of the disease. The tendency of the disease is to extend continuously upon the tissue first involved, and from it to the contiguous tissue. Any operation, therefore, which does not remove the diseased tissue entire does not deserve the name of a radical operation. It is a well recognized fact that in operations upon the mammary gland for malignant disease, every vestige of the gland should be removed; it seems equally important to us that in operations for the removal of the malignant disease of the uterus, every vestige of that organ should be extirpated, and that when this is done the opportunities for benefit to the patient are enhanced.

Extirpation of the uterus is not a new operation, having been done as early as the beginning of the present century; but the results of the operation were so grave as to lead to its discontinuance. West quotes twenty-five cases, twenty-three of which proved fatal. Freund, in 1878, revived the operation of removal of the uterus, but performed it by the vagino-abdominal method. Czerny, in 1879, extirpated the uterus through the vagina, but was so little impressed with the value of the procedure, that his subsequent operations were done by Freund's method; and he did not recur to vaginal operation, until several successful operations had been done by others. Freund's operation was attended by so great a mortality—79 per cent.—that it has been discontinued. The vaginal procedure has continued to grow in favor, until now, the statistics of many hundred operations can be compiled, and nearly a hundred operations enumerated by a single individual. With improved methods of procedure the operation has been expedited, and its mortality greatly decreased. When the operation was performed with ligation of the broad ligaments, with suturing the peritoneum and the vaginal surface, and with complicated methods of drainage the length of time required made the operation a severe test to both patient and physician. Now, when the uterus is encircled by an incision, the vagina pushed off anteriorly and posteriorly until the peritoneum is reached, the uterus depressed into the vagina, and the broad ligaments clamped upon either side, the operation can be performed with great expedition and with less influence upon the system of the patient.

I have had some six cases in which I extirpated the uterus, and five of the patients are now living. The operation has been performed in periods of time varying from fifteen minutes to one hour and a half. The longest time was taken in the first operation, in which, in my efforts to avoid the bladder, I became lost in the anterior wall of the uterus, so that much time was required for the completion of the operation. In the last patient, the uterus was readily drawn down and the operation was completed in fifteen minutes. The broad ligaments may be secured with forceps, or with clamps, such as I show you, in which they are firmly held, and there is no possibility of the tissue slipping or of hemorrhage occurring. These clamps have been objected to, as being unnecessarily heavy, but when we consider that there is a certain amount of sloughing of the tissue, which is compressed in the clamps, this does not seem to be a reasonable objection, as by their weight the broad ligament is brought down and held, so that the peritoneum is glued together before the forceps are removed, permitting the slough to come off outside the peritoneal cavity. Drainage is also favored by the weight of this instrument, and it is still further promoted by the introduction of a tent of iodoform gauze between the two instruments. The clamps are removed at the end of twenty-four hours and the gauze tent at the end of forty-eight or seventy-two hours. The cavity of the vagina is subsequently irrigated by a disinfectant solution.

In the hands of men like Leopold the mortality of this operation has been reduced to about four or five per cent.; and for this reason some of those who originally objected, now advocate it as the preferable plan of procedure. As I have already said, however, it is of limited application. It should not be performed where the disease has extended beyond the uterus, as indicated by infiltration of the broad ligaments. It is not wise; it is not right, to subject a woman to an operation that is attended with a certain amount of danger and with a great amount of anxiety, when it is *certain* not to result in the eradication of the disease. In

those cases, where extirpation is unjustifiable, it becomes difficult to say what should be our method of procedure. Operations of curetting the uterus, and the subsequent application of strong caustics have been highly extolled. This method as introduced by Sims, has been extensively practiced by Van de Warker. I must confess, however, that my own experience in this plan of procedure has been exceedingly unsatisfactory. It consists in curetting and cutting away the diseased tissue until hard and firm tissue is reached, followed by the application of a solution of persulphate of iron upon tampons of cotton, so that the hemorrhage is arrested. At the end of forty-eight hours the clotted blood is removed and the cavity thoroughly irrigated, and this is followed by the application of a caustic. For this purpose chloride of zinc, bromide, and acid nitrate of mercury are used. The chloride of zinc is preferred by most surgeons. It should be used in strong solution, from six drachms to one ounce of the salt to one ounce of water. This is applied by wetting a number of small tampons of absorbent cotton in the solution, and, after squeezing them dry, applying them over the surface to be destroyed. The caustic agent has a greater affinity for the diseased tissue than for the healthy, consequently a marked slough results from the uterus. It is very important that the vaginal surface and the healthy tissue should be carefully protected from the superfluous fluid. For this purpose the walls of the vagina are covered with an ointment consisting of one or two drachms of bicarbonate of soda to an ounce of cosmoline. After the tampons have been carefully applied, they are covered with a dry absorbent cotton, and then with a tampon of cotton wet with a saturated solution of bicarbonate of soda. This solution neutralizes the chloride of zinc with which it comes in contact, and prevents its destructive effects. But even with all this care, it is sometimes difficult to avoid superficial burning and sloughing of the vagina. The operation at best is but a palliative one, and where the disease is not thoroughly eradicated its subsequent progress is rapid.

—Echujin, a glucoside allied to ouabain and strophantin, is the latest addition to the interminable list of African arrow poisons. It is derived from an apocynaceous shrub, adenium boehmianum.

SUPRA-PUBIC CYSTOTOMY IN A CASE OF ENLARGED PROSTATE.[1]

BY W. H. H. COBB, M. D.,

GOLDSBORO, N. C.

Without entering into a history of the varieties of prostrate trouble, or the numerous operations for their relief by surgeons in Europe and in this country—for this has been ably and fully described in a paper before this Association in 1888, by Dr. R. D. Webb—I will simply report a case of enlargement of the right lobe of the prostate, with cystitis and symptoms of vesical calculus, entirely relieved by the operation of supra-pubic cystotomy performed after the method of my friend, Dr. Hunter McGuire.

The patient was a farmer, married, 49 years old, of a rheumatic diathesis, who dates his troubles back to 1881. While attending to the duties of Register of Deeds, he carelessly allowed over-distention of his bladder, and has suffered more or less since that time. In 1882 he had an attack of nephritic colic and passed a small calculus, similar in size and shape to a grain of wheat, and has had slight symptoms since. On three different occasions he passed dark gritty deposits. In 1883 he suffered much inconvenience and some pain in urinating. In 1887 he passed a dark, gristly bloody substance about the size of a corn-pea, accompanied by much pain and bloody urine. For the past three years he has suffered much with cystitis in a very aggravated form, with great pain and difficulty in micturition, his urine containing much blood, pus and mucus. He had consulted numerous physicians, besides taking various patent medicines, receiving but little temporary relief. His efforts to relieve the bladder and bowels were tormenting, and night after night was spent in walking over his premises, with groanings so severe as to disturb his neighbors. There was a constant desire to relieve the bladder, dull pain at the hypogastrium, and pain in the glans penis, a feeling of weight in the rectum with sudden stoppage of urine, which change of position would often relieve, his uncomfortable and painful

[1] Read before the Southern Surgical and Gynecological Association, at Atlanta, Ga., November 12, 1890.

sensations being increased in severity by walking, riding or driving.

This was his condition when he consulted me, June 15, 1890. From this history of the case I suspected vesical calculus, but failed upon examination with the sound to detect any stone; however, a digital examination per rectum disclosed the right lobe of the prostate greatly enlarged, rough, indurated, and exceedingly tender and sensitive. Notwithstanding the failure with the sound to detect a stone, I still thought from the man's symptoms that he might have a stone at the base of the bladder in the posterior prostatic pouch. So distressing were his symptoms that I feared longer delay would result in uretero-pyelo-nephrosis; and so, after consultation by letter with Dr. Hunter McGuire, and with Dr. W. H. H. Cobb, Jr., who saw the case with me, I decided upon a supra-pubic cystotomy as the only hope of securing permanent relief.

On the night of June 22, I gave the man a saline purgative, followed by a warm-water enema early next morning. On the morning of the operation, June 23, I gave five grains of quinine at 5, 6 and 7 o'clock. The patient having been placed upon the operating table, all hairs were shaved off from the pubes to the umbilicus, the parts were thoroughly washed with soap, hot water and nail brush, then with 1 to 2,000 solution bichloride of mercury, our hands, instruments and sponges being rendered thoroughly aseptic. Drs. J. F. Miller, Thos. Hill, M. E. Robinson and W. H. Cobb, Jr., were my assistants.

The patient was fully æsthetized with chloroform, and his bladder was washed out thoroughly through a soft rubber catheter with a four per cent. solution of boric acid, until the returning fluid was perfectly clear and odorless. Having no rectal bag, a soft rubber pessary with a stem was inserted up the rectum, after dilatation, and about ten ounces of warm water were injected in same. Now six ounces of four per cent. solution of boric acid were thrown into bladder through a soft rubber catheter, and retained by rubber band around the penis, while the solution distended the bladder so that it could be distinctly felt above the pubes. Instruments, consisting of scalpel, tenaculum, small forceps, retractors, etc., were placed in a tin tray with carbolic acid and hot water 1 to 40. I began three inches above the symphysis pubis, and made an incision down to the pubic bone, through the skin, fat and cellular tissue, down to the linea alba, which was divided with an incision half an inch shorter from above, the recti muscles were next separated with the handle of the scalpel down to the fascia transversalis, carefully keeping in the median line, using retractors to separate the recti muscles. The fascia transversalis was now incised, shortening the incision another half inch from above. The fat and cellular tissue between the transversalis fascia and the bladder having been separated with the handle of scalpel, the bladder was brought plainly into view. It was caught up with a tenaculum and drawn forward, and a free incision in the lower portion was made admitting the left index finger, which was introduced into the bladder as the scalpel was withdrawn.

The bladder having been thoroughly explored, I must confess that I was disappointed in not finding a stone in the cul-de-sac posterior to the enlarged prostate, as the previous history of recurring calculi, with severe cystitis, pains in the glans penis and sudden arrest of flow of urine, all combined, seemed strongly to warrant the belief in the presence of stone in the bladder, notwithstanding the failure to detect it with the sound. Careful exploration of the bladder failing to reveal a vesical calculus, tumors or other abnormalities to remove, the parts were thoroughly cleansed with antiseptic solution and a No. 15, American scale, soft rubber catheter was introduced into the bladder through the abdominal incision, the distal end of the catheter being placed in a cup by the side of the patient. Three stitches were introduced through the skin only to approximate to some extent the gaping edges of the incision, and the wound was now dressed antiseptically, iodoform, bichloride gauze and absorbent cotton being used. The presence of the catheter in the abdominal incision produced so much vesical tenesmus that it could not be retained in place continuously, and during its absence from the bladder a large sponge was substituted for the absorbent cotton to catch the constantly dribbling urine, which was removed, thoroughly cleansed and rendered antiseptic as often as it became saturated with the urine. The temperature rose to 99½° F. on the evening of the operation, and 100½° F. on the following evening, and at no time

did the pulse exceed 82. Both temperature and pulse became normal on the third day after the operation and remained so from this time on. Hot water enemata were used daily to keep the lower bowel open and to aid in relieving pelvic congestion and in reducing the enlarged prostate. For two weeks the bladder was washed out daily with a four per cent. solution of boric acid, and afterwards on alternate days for about two weeks longer; and the patient's urine was kept acid.

About two weeks after the operation the urine ceased to dribble, and when bladder felt uncomfortably distended, the urine was drawn by the patient, who inserted a soft rubber catheter through the abdominal opening, thus affording the urethra perfect rest. Three weeks after the operation I introduced a hard rubber tube, size 15, American scale, 2½ inches long, and allowed it to remain in the abdominal opening the greater part of the time; the patient withdrawing the plug about every three hours to relieve the bladder. At times, in the patient's movement of his body, the recti muscles would suddenly contract and expel the tube; and so strong were these contractions, that great pain would be induced in attempting the re-introduction of the tube. At no time was the patient able to relieve his bladder through this artificial urethra save with the aid of the catheter or tube. At intervals of every two weeks the prostate was examined and found to be decreasing in size, softening in consistence, and assuming its normal appearance. At the expiration of two months (August 23) I found the prostate perfectly normal, with no symptoms of cystitis, and withdrew the plug, allowing the fistula to unite, which it did in about ten days. My patient now performs the acts of urination and defecation without the slightest trouble, expresses himself entirely relieved, and is following his usual vocation.

REPORT OF A CASE OF LEPROSY.[1]

BY J. H. BERTRAND, M. D.,
DE FOREST, WISCONSIN.

To the great majority of persons leprosy possesses only an historical interest, and it is classed by them in the same category as pestilences and plagues, which formerly devastated countries, but which now are extinct. But, unfortunately, it cannot be so regarded; it is a living and actual reality which the case I have brought before you to-day is a sad proof of.

Case 1. M. M., single, a native of Norway, came to this country at the age of seven years and is now forty years old. The family history on the father's side is good. His father is still living and eighty years old. His mother died of leprosy in this country, at the age of fifty-six years, after an illness of seventeen years. An uncle on the mother's side also died of leprosy. During the first seven years he was in this country he enjoyed good health; at the end of that time, when he was fourteen years old, the disease first made its appearance. The onset was sudden, without any prodromal symptoms. Simultaneously with the appearance of pale, bluish-red spots over the trunk and extremities, chiefly over the extensor surfaces, came chills, fever, loss of appetite, and great prostration, with severe pains in the upper and lower limbs, which was diagnosticated as rheumatism by his physician. The maculæ were present for about two years, when they gradually disappeared, leaving the skin apparently as it was before. During that time they underwent no alteration except to change to a brownish hue. About eighteen months after the onset of the disease, hyperæsthesia made its first appearance, first at the site of the maculæ, and gradually spread over the extremities with increasing intensity. This condition was present for about a year and a half, when it was slowly replaced by anæsthesia, which came on in the same order as the hyperæsthesia, beginning in the maculæ and gradually extending. Towards the close of the third year the man's general condition commenced to improve, the pains in the joints and limbs diminished, and he became able to leave his bed; but it was with difficulty that he could get about, owing to ankylosis of the knee and ankle joints in both limbs. Both wrists and all the small joints of the hands were also ankylosed. The knees and ankles regained their normal functions in about eight months, and he has been able to be about with comparative ease ever since. The wrist joints have only partially recovered; but none of the smaller joints have improved. His condition then remained fair for about seven years, so that he could do light farm work, when he had another period of sickness, which he describes as being like the first attack, and

[1] Read before the Central Wisconsin Medical Society, September, 30, 1890.

which confined him to bed for another three years. Since that time, with the exception of an occasional short interval of a few days, he has been sufficiently well to be up and about up to the present.

During the whole course of the disease there has been no lesion of the mucous membranes nor any tubercles. Whether there has been any thickening of the nerve trunks I have been unable to learn.

The above is substantially the history which this patient gives. His present condition is as follows. He is emaciated and anemic, and his muscles are wasted away. His skin is atrophied, thin, shining and slightly drawn over the subjacent parts. There is no hair on his face. His senses of smell, taste and hearing are normal, but his right eye has been destroyed by an ulcerative process which is still going on, but which is not now painful. The ulceration has destroyed the cornea and sclerotic, but closed up before all of the intra-ocular fluids escaped. New deposits occurred on the surface, forming firm cicatricial tissue, but not sufficiently strong to prevent protrusion of the fluids, so that now there is a dense, horn-like staphyloma which protrudes for about half an inch beyond the eyeball. There is no hyperæsthesia at present, but there is anæsthesia of the hands and arms as far as the elbows, and of the feet and legs up to the knees. There is no regular or symmetrical arrangement of the anæsthesia, nor does it seem to follow the course of the nerves, but affects the entire extremities up to the first large joints. It is so perfect that the patient has himself cut off some of his toes that were falling off, without feeling any pain, and he has on many occasions been severely burnt by unconsciously placing his hands in contact with articles that were hot. Great changes have taken place in the hands and feet from atrophy of the bony, muscular and nervous structures, leading to deformity, ulceration and loss of all but four of the toes. The muscles and tendons of the hands are atrophied and contracted, and all the small joints stand out distorted and rigid, which gives the hands very much the same appearance as is presented in arthritis deformans. Under the right foot there is an ulcer, which has been suppurating for some time, and through which pieces of necrosed bone are occasionally discharged. All of the toes, except the fourth one, have fallen off of this foot. On the left foot the big and little toes are gone.

New York Correspondence.

NEW YORK LETTER.

New York Academy of Medicine.—Bullet Wound of Brain.—Recovery.—Pylorectomy with Gastro-Enterostomy, for Cancer of the Stomach.—Papillitis.—Orbital Optic Neuritis.

Among the more interesting items of the section work at the New York Academy of Medicine for the week ending December 20, 1890, may be mentioned a case reported to the Surgical Section by Dr. J. A. Wyeth. He said that on October 30 a school boy was brought to Mt. Sinai Hospital having a short time before been accidentally shot in the head with a pistol of No. 22 calibre, in the hands of his brother. The shot had been fired at a distance of about three feet and directly in front. The ball had struck the forehead. Beyond profuse hemorrhage and severe pain, there had been no immediate symptoms. On admission the boy was calm and rational; pulse good. About one inch above the middle of right eyebrow a small round wound existed, the edges being depressed. Around it there was some slight swelling. Scattered spots of powder were present in the skin of the face and the clothing was covered with blood. Vision was good in both eyes. The boy had walked into the hospital without assistance. He had been taken immediately to the operating-room. He was there etherized and, the external parts having been thoroughly cleansed, an incision two inches long was made at the site of the bullet wound and parallel to the eyebrow. The periosteum was raised and loose pieces of bone were found in the wound, consisting partly of spiculæ of considerable size from the inner table. Fluhrer's probe was passed into the wound to a distance of a quarter of an inch. The patient had then begun to vomit. A finger was placed over the wound, and on this being raised there was a sudden gush of dark clotted blood and particles of white brain substance. The wound was washed out with bichloride and packed with iodoform gauze secured with a tight bandage. On November 3 the boy's temperature had risen to 104°, and there had been some delirium. Ice bags had been applied to the head. On the following day the wound, on being dressed, was found to be aseptic. After this dressing the temperature had

fallen to a little above normal and had so continued. On November 8, upon removal of the gauze, about half an ounce of blood-clot and broken-down brain substance had welled up from the opening. No evidence of any suppurative process had existed in the discharged material at any time. During the progress of the case the patient had experienced more or less pain in the region of the occipital bone and in the right ear. He had continued to improve and on November 25 his temperature was reported as normal, and the ice coil was stopped. On December 7 the wound was found to be entirely healed and the patient was suffering no pain; he was bright, cheerful and did not seem to suffer any inconvenience from the loss of brain tissue or from the presence of the bullet in the cranial cavity. Care would be taken to keep him quiet for some time yet in order to give the bullet the best possible opportunity to become encysted. The speaker wished to give his late house-surgeon, Dr. Weber, due credit for his successful management of this interesting case.

In the discussion which followed, the opinion was freely expressed that the Bell Telephone Co. should be again urged to withdraw its obstructive decision, which prevented the utilization of certain processes for the localization of bullets within the cranial cavity, and Dr. Gardner explained that he had found out a method by which the ordinary telephone connections might be arranged to do the necessary work, and

Dr. W. T. Bull then related the histories and the details of the operations in three cases of cancer of the stomach. He thought that it was strange that in this country where so much good work had been done both scientifically and practically in abdominal surgery, so little effort had been made for the cure of cancer of the pylorus. It was thought that the operation of pylorectomy had been simplified by the introduction of Senn's plates, and that the mortality would be much diminished. Another departure from the typical resection was the combination of pylorectomy with gastro-enterostomy, the cut edges of the stomach and duodenum being shut off so as to form a cul-de-sac, and the anostomosis being made between the stomach and the jejunum. This has been the method employed by Dr. Bull in his three cases. In the preparatory treatment the stomach-pump was employed after the patients were under the anæsthetic. This Dr. Bull thought a more effective way of emptying the stomach, than the old method of several washings out previous to the anæsthetic. The median incision had proved the most satisfactory, and was to be preferred to any other. He used no clamps on the stomach or duodenum to prevent escape of contents. The fingers of an assistant he considered more satisfactory, especially if with the aid of hooks or loops of silk the divided ends of the viscera were kept elevated in a vertical position. A plug of iodoform gauze was introduced into the duodenal opening, and a flat sponge in the stomach. There was but slight bleeding from the stomach or intestinal wall, and that which followed the incision for the anastomotic opening was effectually controlled when the catgut rings were approximated. The loop of jejunum was shut off with strips of iodoform gauze while the anastomosis was being made. The continuous catgut suture through the mucous membrane, reinforced by interrupted sutures, were used to close the cut edges of the stomach and duodenum. In using the rings Dr. Bull always added to the silk sutures, which held them in apposition, a line of continuous suture, with an isolated suture where he thought it necessary. He looked upon the rings, not as an absolutely sure method of uniting serous surfaces, but as a most convenient adjunct to a carefully applied peritoneal suture. In all of his cases the gastro-enterostomy had been perfect in point of accurate and secure apposition. One of the patients operated upon by the speaker was now alive and at the last hearing was in good health. He thought that the fatal result in the other two cases could be traced to faults in the technique; in one case, at least, there was no doubt of this, as the autopsy showed that a sponge had been unfortunately left in the stomach.

Statistics showed that out of some thirteen hundred cases of cancer of this region one-half had involved the pylorus. Half of these again were uncomplicated by any involvement of the glands. Therefore half the cases of pyloric cancer were really amenable to treatment by operation. He believed that death in these cases often took place from the effects of the mere mechanical obstruction long before the disease had exhausted the patient. The hydrochloric-acid test and other means now at disposal for careful and accurate diagnosis in these cases should render an early interference possible and then with perfected technique

he thought that the operation of pylorectomy might be raised from its present position to that of a life-saving and life-prolonging procedure.

Dr. Robert Weir after critically analyzing the mortality percentages after the operation of gastro-enterostomy as against those of resection of the pylorus, thought that the latter operation had been performed a sufficient number of times and had been attended as yet by such fearful mortality, and had proved of such little use in prolonging lives that it ought now be relegated to a place among the experimental procedures.

Dr. Robert Abbé thought that if the operation of resection of the pylorus had only yielded fifty per cent. of satisfactory results, and took three hours to perform, then no surgeon of only general experience and ability should attempt it. Gastro-enterostomy, when its technique was more thoroughly written upon and more properly illustrated, should be possible to any man who could handle knife, scissors and needles.

Dr. Bull did not wish to be understood as advocating resection of the pylorus in cancer of this region, but thought it was the duty of surgeons to undertake the operation when there was a chance of success attending their effort.

The proceedings at the last stated meeting comprised the consideration of certain lesions of the visual tract from the eyeball to the cerebral cortex. In this relation Dr. C. S. Bull, in a paper on Papillitis, expressed the opinion that the most common cause of this condition was intracranial disease and that of the intracranial lesions tumor was the most frequent. The frequency and severity of the papillitis did not seem to be materially influenced by either the nature, the size, or the location of the tumor.

The next most frequent cause was meningitis, then followed abscess of the brain, hydatid disease and softening from thrombosis or embolism. Papillitis was also occasionally met with in acute diseases of the spinal cord. Dr. Bull then gave a synopsis of the various views as to causation which have been from time to time held and promulgated by distinguished authorities. In summarizing his own consideration of the subject, the speaker said that optic neuritis, limited to or most intense in the optic disc, might occur without any apparent intracranial disease. Pure papillitis was known to occur in simple anemia. It seemed therefore fair to conclude that the intra-ocular end of the optic nerve was a structure peculiarly prone to inflammation. It was a difficult matter to connect papillitis with increase of intracranial pressure for it was the rare exception in chronic hydrocephalus, where the intracranial pressure was raised to the highest point of which we had any knowledge. On the other hand in cases of intracranial tumor with papillitis there might be no sign of increased intracranial pressure during the life of the patient. There might also be signs of increased intracranial pressure in cases of tumor without papillitis. If we rejected the theory that pressure on the cavernous sinuses was the immediate cause of this condition we could not absolutely ignore its influence on the retinal circulation. The great distention of the veins and the narrowing of the arteries took place mainly when the inflammation had reached a high degree of intensity and these facts pointed to the inflammation in the nerve as the cause of the strangulation by pressure on the vessels. This view was confirmed by pathological investigations. The conspicuous constriction of the vessels was always in the papilla in front of the sclerotic. The most intense signs of strangulation might be seen in cases in which there was no reason to suspect the presence of intracranial disease. Distention of the optic sheath was frequently met with in cases of tumor with papillitis. It might also be absent in cases of tumor with internal hydrocephalus. It had been suggested that the fluid might be found within the sheath itself. If the sheath was the main lymph channel by which the fluid was conveyed from the eye, its distention in optic neuritis by fluid escaping from the papilla was easily understood. But there was good ground for believing that the fluid found in the sheath passed into it from the subarachnoid space. Dr. Bull said he really knew very little of the relation which might exist between dropsy of the sheath and optic neuritis. The occasional occurrence of papillitis without it showed that it was neither the invariable nor the chief mechanical cause of papillitis. It therefore seemed proper to draw the inference that we could not decide in any given case against the existence of a descending neuritis from examination of a small portion of the trunk of the optic nerve, and that a pathological change in the nerve deviating but slightly from the normal state might convey a condition of irritation to the eye which was sufficient to set up actual papil-

litis. It also seemed proper to draw the following conclusions in regard to the development of papillitis in intracranial disease: (1). In cases of cerebral tumor, evidence of descending inflammation may be traced in the sheath or nerve much more commonly than is generally supposed, while in cases of meningitis the evidence of descending inflammation is almost invariable. (2). The resulting papillitis may be slight or may grow intense, but we are ignorant of the cases which bring about this difference. (3). The mechanical congestion in these cases of papillitis does not always result from compression of the vessels behind the sclerotic ring, but does always follow compression from inflammatory exudation in the papilla. (4). Slow increase of intracranial pressure has no effect on the retinal vessels, but sudden increase of such pressure may intensify a papillitis originating in some other way. (5). Distention of the sheath alone is probably not sufficient to cause papillitis by its mechanical effects, but it may intensify the process otherwise set up.

In a paper on optic neuritis, including alcohol and tobacco amaurosis, Dr. A. Knapp said that the cases in which people notice a haze, a blurr, even a perfectly dark patch in the centre of their field of vision, known under the name of central amblyopia or central scotoma, as well as those cases in which persons lose their sight in one or a few days without exhibiting any ocular or general disease to account for it, were explained more than twenty years ago by A. Von Græfe and Theo. Leber. They supposed the condition to be an inflammation of the orbital parts of the optic nerve, retro-bulbar neuritis. This hypothesis has since been proven to be a reality by anatomical investigations. Retro-bulbar neuritis might be idiopathic or the result of different kinds of intoxication, alcoholism, nicotinism, lead poisoning, diabetes, syphilis, etc. The condition might take on an acute or chronic form. A number of very interesting microscopic specimens were exhibited to the society. One showed the central interstitial neuritis in the period of nuclear infiltration, another in the stage of connective tissue hypertrophy. The process was characteristic by the limitations of its area of inflammation, circumscribed and triangular near the disc. In one specimen the changes passed like a band from the temporal border of the nerve across to the nasal side. This explained how the atrophy of the nerve might become total. In all of the specimens a certain number of healthy nerve fibres were seen preserved in the atrophic parts. This showed how in alcoholism, that total blindness was rare, and how, on the other hand, in the field of vision of persons blind from retro-bulbar neuritis islets of useful sight were permanently preserved. Retro-bulbar optic neuritis presented an example of peripheric neuritis of great practical importance.

PERISCOPE.

Immunity to Tetanus and Diphtheria.

The two researches on immunity, of which our Berlin Correspondent telegraphed a brief summary last week, not only have a special interest at the present time, when the attention of the whole world is rivetted on the remarkable discovery of Koch for the cure of tuberculosis, but possess also great intrinsic merit. The paper on the Production of Immunity against Diphtheria and Tetanus in Animals, in the *Deutsche Medicinische Wochenschrift*, December 4, 1890, by Drs. Behring and Kitasato, is, perhaps, the more important of the two. These two observers have been engaged for some time in a study of the nature of diphtheria and tetanus, and they have at length succeeded in not only conferring immunity on animals against attacks of either disease, but also in arresting the disease after it has already set in.

The manner in which this is brought about is reserved for a later communication. In the present paper they deal with the subject only so far as to prove the correctness of the following proposition: "That the immunity which can be conferred on rabbits and mice against tetanus depends on the power possessed by the serum of the blood to render innocuous the poisonous products formed by the tetanus bacilli."

This explanation of the nature of immunity has not been distinctly given in any of the publications which have hitherto dealt with the subject. The views hitherto held regarding the nature of acquired immunity have been three—in the doctrine of phagocytosis, which seeks for an explanation in the activity of living cells; the bacteria-killing power of the blood; and lastly, acquired toleration. When any two of these

have failed to explain the phenomena of immunity, or have been proved by experiment to be false, this has been regarded as a proof by the process of exclusion that the remaining one was right. Thus Bouchard, in his recent address before the International Medical Congress, declared: "Let us speak no more of an education of leucocytes, and a toleration of cells to the action of bacterial poisons; it is the bacteria-killing power of the body which constitutes what we term vaccination, or acquired immunity."

One of the present observers (Behring), in the course of his investigations on rats and guinea-pigs rendered immune against diphthera, failed to find either of the above explanations satisfactory. The explanation was at last, after many failures, found in the bacteria-killing power possessed by the blood of animals immune to the diphtheria bacilli. This explanation was then found to apply also to tetanus. The results of their observations they sum up as follows:

1. The blood of rabbits rendered immune against tetanus possesses bacteria-killing properties towards the tetanus bacillus.

2. These properties belong also to extravascular blood, and to the serum obtainable from such blood.

3. These properties are of such a durable nature that they remain active even in the bodies of other animals, so that it is possible to obtain good therapeutic results by the operation of serum or blood transfusion.

4. These properties are entirely absent from the blood of such animals as are not immune against tetanus; and when the poison of tetanus is introduced into these animals, it can be found after death in the blood fluids of the body.

The following are some of the observations on which the above conclusions are based:—Their method of conferring immunity against tetanus they reserve for a coming paper. A rabbit was rendered completely immune against tetanus, the degree of immunity being such that 10 cubic centimeters of a virulent tetanus culture was entirely without effect, while ½ cubic centimeter sufficed to kill an ordinary rabbit. It was found that the animal had acquired immunity, not only against the living tetanus bacilli, but also against the poison. It could withstand, without ill effect, twenty times the dose required to kill a healthy rabbit. Blood was withdrawn from the carotid of this animal. Of this fluid blood 0.2 cubic centimeter and 0.5 cubic centimeter were injected into the peritoneal cavity of two mice. Twenty-four hours later both were inoculated with virulent culture of tetanus, two healthy mice being at the same time inoculated with the same culture. While the latter died in twenty-four and thirty-six hours respectively, the two former remained perfectly healthy.

The greater quantity of the blood was allowed to stand till the serum had separated. Of this serum, 0.2 cubic centimeter was injected into the peritoneal cavity of six mice. Inoculation of these twenty-four hours later with virulent tetanus proved without effect, the mice remaining quite healthy, while the mice used as control experiments all died in forty-eight hours.

It is also possible to obtain good therapeutic results with such serum, by first inoculating the animals and then injecting serum into their peritoneal cavities.

Further experiments were also made showing the intensely destructive action of this blood serum against the tetanus poison. A tetanus culture ten days old was taken and filtered, so as to be free from all spores. Its virulence was such that 0.00005 cubic centimeter sufficed to kill a mouse in four to six days, while 0.0001 cubic centimeter killed it with certainty in less than two days, 0.5 cubic centimeter of the serum of the immune rabbits was mixed with 0.1 cubic centimeter of this culture, and allowed to act for twenty-four hours on the tetanus poison contained in it. It was then found that mice could withstand 0.2 cubic centimeter to 0.033 cubic centimeter, or 300 times the dose necessary to kill healthy mice. The mice remained quite healthy, while the control mice died in six hours, after a dose of only 0.0001 cubic centimeter.

All the mice rendered immune in this way have remained so; they have been repeatedly inoculated with virulent tetanus cultures without the slightest ill effect. This fact is the more remarkable since in the many experiments that have had to be made not a single mouse or rabbit has ever been found naturally immune against tetanus, and furthermore all the attempts made in the laboratory for a long time back by other methods to render these same animals immune have completely failed. Thus the conclusion may be drawn that the explanation of the nature of immunity given above is one capable of wide application. In all cases control experiments were made with the blood and serum of rabbits not immune.

Both blood and serum proved to be entirely inactive. The same was found to apply to the serum of oxen, calves, horses and sheep.

It was also found that the blood of such animals while in the vessels was destitute of such tetanus-destroying properties. Thus rabbits injected subcutaneously with 0.5 cubic centimeter of a virulent tetanus culture, free from spores, died in five or six days with all the symptoms of tetanus well pronounced. In such cases on *post-mortem* examination a serous effusion was found in every case without exception in the pleural cavities. On the average 0.3 cubic centimeter of this fluid sufficed to give a mouse tetanus and to kill it, and the blood of such animals was capable of giving rise in turn to tetanus when injected into other animals.

The application of these most striking results to the cure or prevention of these two diseases in man is reserved for future consideration. The authors, however, aptly conclude their communication by drawing attention to the support given by their results to the view at all times widely held, and fitly described by Goethe in the words of Mephistopheles to Faust:

Das Blut ist ein ganz besonderer Saft.

These words derive a new and altogether special significance from the result of recent bacteriological observations.

The second paper is a continuation of one which appeared early in the present year by Brieger and Fraenkel, entitled "Researches on Bacterial Poisons." The main points of this paper were noted in the *British Medical Journal* at the time of its publication. The present contribution to the same subject is from Fraenkel alone, and deals with the methods of producing immunity against diphtheria. It will be remembered that in the paper referred to these two observers endeavored to show that the pathogenic action of a number of organisms was to be attributed to certain products of their activity of an albuminous nature; to these bodies they gave the name of "toxalbumins." The disease most thoroughly studied in this connection at that time was diphtheria. They considered the most characteristic features of these toxalbumins to be, first, their albuminous nature, and, secondly, their peculiar action on the organism. The latter, in many respects, resembled that of ferments, but they were unable to regard them as ferments, for this reason, that while, according to them, the action of ferments is more or less independent of the quantity present, in the case of toxalbumins the dose was the most important factor. The larger it was the more rapid and complete was their action, and they lost their power altogether when the dose fell below a certain limit. In this respect, therefore, they resembled in their action ordinary vegetable and mineral poisons.

Fraenkel's later observations, here communicated, deal with the artificial production of immunity against diphtheria.

There are two ways in which the body may be protected against the attacks of pathogenic micro-organisms. The first of these we owe to Pasteur. In it use is made of cultures, the virulence of which has been lessened in various artificial ways—by heating, etc. In the other method use is made of the various products of bacterial activity —completely free from the organisms themselves. Of the comparatively numerous researches that have already been carried out by various observers in this latter domain; those of Smith, Chamberland and Roux, Beumer and Peiper, Gamaleia, Bouchard, Charrin are here referred to; that of Hankin, who succeeded in isolating the very substance which confers immunity against anthrax, is, however, not mentioned —an omission all the more to be noted as his work is the most conclusive of all, and was carried on in the same laboratory as that in which Fraenkel worked.

Both the above methods have been used by Fraenkel in his present research. Little difficulty was experienced in weakening the bacilli of diphtheria either by heating their cultures to a certain high temperature, or by adding some antiseptic agent, such as potassium bichromate or gentian violet. The results obtained in this way were unsatisfactory and uncertain, the weakened cultures varying much in their activity, and very readily, under certain circumstances regaining their virulence. He found it impossible to confer immunity, even in a small degree, by this means.

In his experiments with the products of their activity, he used at first toxalbumins which had been kept in a dry condition for many months without losing in any way their poisonous properties. These failed entirely to confer immunity against the disease. It appeared, indeed, as if the animal inoculated with this substance in small doses died more quickly after subsequent inoculation than healthy animals.

Better results were obtained when, instead of the toxalbumins, he employed the fluids obtained by filtering the cultures through a porcelain filter, or heating them for an hour to a temperature of 55° C., thus freeing them from all living elements. Some of the animals injected with these cultures gained a certain tolerance of the diphtheritic poison, dying, for example, three, four, six and nine days after an injection of 0.1 cubic centimeter, instead of in thirty to thirty-six hours, as in the case of untreated animals. They all died, however, none of them acquiring a complete immunity. This result, such as it was, satisfied him that he was on the right track.

A further advance was made when, instead of small quantities, he used larger quantities of these culture fluids. The filtered culture, or the culture itself, was heated for an hour at a temperature of 100° C., and 10 cubic centimeters injected subcutaneously into guinea-pigs. A few of the animals so treated survived subsequent inoculation with virulent diphtheria; the great majority of them, however, died, although at later periods than usual, namely, after two weeks and a half.

He finally found that a temperature of 65° to 70° C., maintained for an hour, yielded the best results. Injections of 10 to 20 cubic centimeters of a culture of diphtheria bacilli so treated rendered guinea-pigs immune against subsequent injections of even the most virulent poison. Even this conclusion required modification, for it only applied when the subsequent inoculations were made not earlier than fourteen days after immunity had been conferred. If made sooner, the result was uncertain, some animals dying, others not. In the first few days after the injection the resistance of the animal seemed, indeed, to be lessened, the animals dying more rapidly and certainly than before, when inoculated with virulent cultures.

Furthermore, the immunity in this way conferred only applied against subsequent subcutaneous inoculation, and not to subsequent inoculation of mucous membranes—such as the vaginal—with diphtheria. To this extent, therefore, it is imperfect, and considering the ordinary method of propagation of diphtheria in man through the mucous membrane, this result obviously leaves a wide blank still to be filled up before we can apply these results obtained on animals to man.

The remaining portion of the paper is taken up with a consideration of the nature of the body which confers this immunity. Fraenkel concludes that it is quite distinct from the one that produces the poisonous symptoms, that while the latter is destroyed at a temperature of 55° to 60° C., the former is not destroyed till a temperature of 100° C. is reached, although it is weakened at any temperature above 90° C.

The best temperature, therefore, at which to heat the cultures so as to destroy their toxic properties without destroying those on which their power of conferring immunity depended is 66° to 70° C. This substance which confers immunity has no therapeutic properties. So far, indeed, from this being the case, its injection into animals previously suffering from diphtheria rather hastens their death.—*British Medical Journal*, December 13, 1890.

The White Blood Corpuscles in Croupous Pneumonia.

Dr. T. S. Kikadze, in the *Bolnitchnaya Gazeta Botkina*, May 16, 1890, reports investigations of the blood in a large number of cases of croupous pneumonia during the course of the disease. He describes minutely the methods and precautions used in the work.

The results are represented in diagrams which show distinctly the possibility of predicting the character that the disease will assume in its course, the prognosis, and in case of poor prognosis, the treatment which is proper to lessen the gravity of conditions. The conclusions are:

1. During a normal course of croupous pneumonia the absolute, as well as the relative, number of white blood-cells is mostly increased to twice or three times the normal number.

2. In fatal cases of croupous pneumonia no increase is observed, and sometimes there is actual diminution of the same.

3. The increase in the number of leucocytes is on account of the mature and degenerating elements of the white blood-cells.

4. The above-cited changes in the blood take place early in the disease, earlier than any pulmonary changes show themselves.

5. Once taken place, the above changes remain with little variation until the occurrence of crisis.

6. Just before the crisis takes place there is a sudden increase of the number of leucocytes; the latter is supposed to be due to the re-entrance of the leucocytes from the pulmonary alveoli into the blood-vessels. This view is supported by the fact that at the same time there is an increase in the number of degenerating leucocytes.

7. The increase in the number of the normal leucocytes and of those in process of degeneration is parallel with the body temperature.

8. During the period of fever in croupous pneumonia the blood elements show evidences of delayed morphological metamorphosis, which is seen from the elements being in a condition ready to disintegrate.

9. The red blood-cells are progressively decreased until the end of the disease.

10. The temperature and blood crisis occur synchronously. The number of the leucocytes and the body temperature fall suddenly to the normal or subnormal; the amount of the breaking-down elements is diminished accordingly.

11. During the day of crisis the blood shows evidences of hastened morphological metamorphosis in the sense above mentioned.

From the large number of pneumonic patients examined, the author found that the increase in the leucocytes is independent of the area of pulmonary involvement, the intensity of the inflammatory process in the lungs, or the period in the course of the disease. It has nothing to do with the pathological pulmonary process. It depends upon something that is not yet known, but which the author suggests is a pneumococcus, or some other pathogenic microbe, or the products of its vital changes, which fill the blood, secondary to which the local pulmonary manifestations show themselves.

With disappearance of the as yet unknown cause, the blood and temperature crisis takes place. In many cases the author predicted the approaching crisis of temperature because of the decrease in number of the leucocytes, before the temperature took place.

In view of the fact that an increase in the number of leucocytes in the beginning of croupous pneumonia is necessary to a good issue of the disease, the author suggests to use camphor early, when the increase is absent, because camphor increases the number of leucocytes twice and sometimes thrice the normal.

Leprosy in Norway.

In an interesting account of a visit to the Hospital for Lepers at Molde, Norway, published in the *Edinburgh Medical Journal*, November, 1890, Dr. W. Allan Jamieson describes its beautiful situation and its capacity, and discusses certain points in regard to the disease. Himself apparently a believer in the contagiousness of leprosy, he says that Dr. Kaurin, the Physician to the Hospital, is a full believer in the communicability of leprosy. He adds that there are, however, some curious points with respect to this. In Norway no nurse nor any medical man in attendance on lepers has, so far as is known, ever yet contracted the disease, nor have any experimental inoculations on animals been successful. Physicians have inoculated themselves, their colleagues and numerous healthy persons, introducing the leprous material in the form of portions of the nodules under the skin, but no one so treated has yet become a leper. To communicate the disease two factors would appear necessary—one, prolonged or very intimate contact with a leper, as by sleeping in the same bed, wearing the clothes of an affected person, etc.; the other, a peculiar condition of the system, probably induced by habitually partaking of a bad or at least unsuitable dietary. Mr. Jonathan Hutchinson, as is well known, holds strongly that fish is probably the vehicle by which the poison of leprosy gains access to the human body. Medical men have not yet generally adopted his view, but from several conversations which Dr. Jamieson held with intelligent Norwegian peasants as to their opinion of the cause of leprosy, it seemed evident to him that they were inclined to think that fish had at least something to do with its origin or spread. If such a view is, even to a limited extent, correct, there can be no true ground for any leprosy scare as far as England is concerned. There is no reason to fear that, under existing conditions, leprosy will again obtain a hold in Great Britain. Dr. Jamieson weakens his article a little by introducing an *ad captandum* argument founded upon the fact that a physician who holds strongly the view that leprosy is non-communicable once visited a Norwegian leper hospital, and there expressed his opinions freely and decidedly. "Will you then occupy a bed alongside of one of these patients?" asked the doctor in attendance. "No," replied

the anti-contagionist, thus put to the proof after a fashion he did not anticipate, "I have a wife and children at home depending on me." Dr. Jamieson says: He had not, and perhaps one could scarcely expect him to have, the courage of his opinion. This may be so, or not; but it has no bearing whatever upon the correctness or incorrectness of his opinion.

Risks of Cocaine Injections.

The *Medical Press*, November 5, 1890, says that two warning cases are reported from France. In one of them, which occurred at Lille, the patient died, and the dentist who gave the injection was acquitted of neglect, but condemned for practicing medicine without qualification. In the other, which occurred at Paris, the patient was with great difficulty brought round by hypodermic injections of ether. The cocaine injection was also made in this case by a dentist.

In another place the same journal says that the Lille dentist who was charged with causing the death of a girl by injecting cocaine in order to procure anæsthesia, has been sentenced to a fine of fifteen francs for breach of the law regulating the practice of medicine, the judgment endorsing the view that cocaine is an anæsthetic which requires to be used with prudence, and cannot legally be administered by other than a qualified medical man.

Exfoliation of the Bladder in the Female.

The *Glasgow Medical Journal*, October, 1890, quotes from the *Edinburgh Medical Journal*, June, 1890, that Haultain narrates a case of exfoliation of the bladder in a woman, due to retention produced by incarcerated retroverted gravid uterus. Microscopic examination showed the sac, which was expelled through the urethra, to consist of the bladder wall in its entire thickness. Haultain is of opinion that many cases which have been reported as exfoliation of the mucous membrane have really been of the entire thickness of the wall, as in his own case. By others the condition has been confused with exfoliation of a croupous false membrane. The cases published, occurring in females, have all been associated with one of two conditions—retention of urine or labor; the retention of urine being due in all cases but one to incarcerated retroposition of the gravid uterus. Experiments on dogs by May, of Giessen, have shown that retention of urine is of itself sufficient to cause death of the bladder. When the condition is the result of retention, Haultain considers that this is brought about by pressure of the retained column of urine on the veins of the neck of the bladder.

In those cases of labor where it occurs without retention, the pressure on the vesical neck will affect both arteries and veins, so as to produce complete arrest of the circulation. Of 33 cases of exfoliation of the wall in more or less entirety, to which reference is made, there were only 8 fatal.

The formation of an adventitious receptacle for the urine would seem to take place by the agglutination of adjoining pelvic viscera, and the organization of inflammatory products. The amount of control over the urine may be expected to vary with the extent to which the muscular coat, and more especially the sphincter fibres, have survived.

Protopine—A New Opium Alkaloid.

Protopine was first isolated from opium in 1870 by Hesse. It has a formula of $C_{20}H_{19}O_5$, and is present in but small amount. Since then its presence has been detected by Eykmann in the *Macleya cordata*, and by Selle in the *Chelidonium majus*, plants which also belong to the family of the Paveraceæ.

Dr. Engel has recently made some experiments on cold-blooded animals (frogs) and warm-blooded animals (guinea-pigs, cats and rabbits) to determine the physiological properties of protopine, and his results, which are summarized in the following statements, are published in the *Gazette Médicale de Paris*, October 11, 1890:

1. In small doses protopine exercises on the frog narcotic effects similar to those produced by other opium alkaloids.

2. In large doses it produces a paralyzing action on the muscular substance, and on the terminal ramifications of the peripheral nerves.

3. With small or moderate doses reflex action is not abolished, although this occurs when large doses are given.

4. Protopine produces toxic effects in mammals comparable to those produced by camphor, death being produced by a paralysis of the respiratory centre.—*Therapeutic Gazette*, November, 1890.

THE

MEDICAL AND SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

EDUCATION AND THE DISEASES OF SCHOOL-CHILDREN.

The object of education should be to fit the pupil for the hightest degree of usefulness possible *to him*. This implies that the pupil is an individual; that some knowledge may be useful to one and not to another; that different pupils are capable of assimilating varying amounts of the same form of knowledge. Childhood is the most critical time of education. Then thoroughness rather than extent of knowledge should be aimed at. Later on in life, when one has mastered a business or profession, it will be found that an acquaintance with a variety of subjects opens up many avenues through which one may receive pleasurable impressions, while at the same time it makes general social intercourse enjoyable, and enlarges the circle of friends. But in early life the rule should be *multum*, not *multa*, lest the child grow up with a smattering knowledge of many things and without knowing one thoroughly. Above all, it should never be forgotten, in the education of a child, that the most important consideration is health. A child is not educated for childhood, but with a view to ultimate usefulness when fully grown; and every one knows that, to the average person, a sound body is more important for success in life than a well-stored mind.

These remarks have been suggested by an article in the *Revue Médicale*, August, 1890, which refers to a question raised by Dr. Axel Key before the last International Medical Congress, at Berlin. Dr. Key asked if modern education either at home or at school is well adapted to its purpose and calculated to give children a sound mind in a sound body? In the course of his inquiry he made some interesting statements. Boys, he says, pass through three different periods of development: An important growth takes places when they are about seven or eight years old, another, but less considerable increase from their ninth to their thirteenth year; and at puberty—from fourteen to sixteen years of age—there is a remarkable and very rapid increase in height and weight. Girls pass through the same stages, but the stages appear some years earlier than in boys. As regards differences in social position, those in good circumstances are a year in advance of the poor of the same age, showing that poverty and faulty conditions of existence retard the development of children.

Key also says that children do not gain much in height from the end of November to the end of March; from March to July, height increases much, but not weight; while from July to the end of November, gain in height is very slight; but there is a great gain in weight—the daily gain in weight being often three times greater than during the winter months. When summer vacations

are early, they give opportunity for a very great gain of weight.

The observations of Key have a bearing upon the subject of the education of children; for they serve to give point to the trite remark about childhood being the time for physical growth and development.

The effect of ill-regulated conditions of education may be seen in Sweden, where, Key says, one-third of the secondary scholars are sick or afflicted with chronic affections. Myopia increases in frequency uninterruptedly from one class to the following, while thirteen and five-tenths per cent. of the boys have habitual headache, and nearly thirteen per cent. are chlorotic. Of the girls, nearly thirty-six per cent. are said to be chlorotic, while an almost equal number suffer from habitual headache ; ten per cent. at least, have curvature of the spine.

It is not fair to attribute all the defects found in school-children to the school and to study. Many of them would be operative out of school. The points, however, which we have sought most to emphasize are that childhood is the most critical educational period ; that children should be taught to "see straight and think clear," to adopt correct methods of study, to learn thoroughly rather than to learn many things ; and that in their studies they should be treated as individuals as far as possible, their special requirements and probable ultimate destinies being noted, and their mental and physical disabilities being taken into account. These desirable things are well nigh impossible in our public schools, for the classes are all large, rarely numbering fewer than fifty. The chances of a child are better in a small private school, especially along with careful home encouragement, and are probably best of all under a wise man as a private tutor.

SURGEON-GENERAL SUTHERLAND.

The nomination and confirmation of Colonel Charles Sutherland, to be Surgeon-General of the Army is such an excellent choice that we congratulate the President and the army upon it: the President because he has acted upon a principle which is admirable in every department of the public service, and the army because it will have a Surgeon-General who is an honorable man and a most excellent officer. More than this, the choice is one which will give support to the idea—so essential to good feeling in the army—that faithful and continuous service counts for something when questions of advancement arise.

Colonel Sutherland was Senior Surgeon of the Medical Corps, and has—as the *Philadelphia Ledger* says—earned his promotion by honorable and meritorious service on the field of battle, as well as in the hospital—in war as well as in peace. He is as reserved in matters of personal preferment as he is forward in all matters in the line of his professional and military duty ; and his promotion to the Surgeon-Generalship is due, we believe, entirely to his creditable and honorable record.

Dr. John S. Billings, whose name is so familiar to the medical world, was strongly urged for appointment, and would, we feel sure, have admirably filled the position, but we think the President did well to resist the pressure to appoint Dr. Billings, who will, no doubt, wait without repining until his turn fairly comes. Meanwhile the army and the medical profession will continue to have his valuable services, and he will not have to contend against the difficulties inseparable from a promotion over his seniors in service.

APPOINTMENT OF A LECTURER ON THERAPEUTICS AT THE JEFFERSON MEDICAL COLLEGE.

The Committee of the Trustees of the Jefferson Medical College, appointed to select an instructor to fill for the remainder of the college term the chair of Materia Medica, General Therapeutics and Hygiene, lately occupied by Professor Roberts Bartholow, on December 12 named Dr. Albert P. Brubaker for the position.

When the action of the Trustees in ap-

pointing the committee for this purpose became known, the students of the College who had favored Dr. Brubaker's selection started a petition to the faculty to that effect, and in a short time, it is stated, it had over five hundred names on it. On the petition coming before the Faculty, that body appointed a committee to confer with the committee of the Trustees, with the result noted above.

Dr. Brubaker is a graduate of the Jefferson College, of the class of 1874. In 1879 he was appointed Demonstrator of Experimental Physiology in Jefferson College. From 1885 to 1889 he was Demonstrator of Experimental Therapeutics. Since 1885 he has also been Professor of Physiology in the Pennsylvania College of Dental Surgery.

In making this appointment we believe the Trustees of the Jefferson College have found a happy solution of the difficulties into which they were precipitated by Dr. Bartholow's retirement. Time is afforded to see if Dr. Bartholow can resume his work, or to find a successor who will add to the reputation and success of the College; which meanwhile will have the services of an excellent lecturer on one of the most important branches of its curriculum.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE SCIENCE AND ART OF OBSTETRICS. By Theophilus Parvin, M. D., LL. D., Professor of Obstetrics and Diseases of Women and Children, in Jefferson Medical College, Philadelphia. Second Edition, revised and enlarged. Illustrated with 239 wood-cuts, and a colored plate. 8vo, pp. 704. Philadelphia: Lea Bros. & Co., 1890. Price, Cloth, $4.25; Leather, $5.25.

The early appearance of the second edition of this work is evidence of the favor with which the first edition was received. Parvin's *Obstetrics* is universally conceded to be one of the best manuals extant. The author has drawn more largely upon French literature, and leans more strongly towards French practice than is the case with other English and American authorities. This feature of the book renders it a more real addition to American literature. The style throughout is admirably clear and pleasant, and remarkably free from dogmatism. The reader is thus left to form his own judgment when authorities differ.

Appearing at this time, when the subjects of extra-uterine pregnancy, placenta prævia, and the Cæsarean section are attracting such merited attention, it will be interesting to observe the position of so conservative a man with reference to these subjects.

While tubal pregnancy is considered by far the most frequent, all the varieties of ectopic pregnancy are admitted, or at least are not rejected, and ample citations from the literature of the subject are given. The work of Mr. Tait is fully appreciated—although his theories are by no means all accepted—but is not permitted to obscure the work of older and contemporaneous men. Ectopic pregnancy is estimated to occur once for every five hundred cases of pregnancy. This estimate is far higher than the usual one, but is amply supported by accumulating evidence. Salpingitis is regarded as the usual cause of ectopic pregnancy. The question of diagnosis is admirably presented. Broadly speaking, abdominal section and removal of the gestation cyst is recommended, whenever ectopic pregnancy is diagnosticated. After considering the question of electrical treatment, the author says: "No impartial reader of the reports of cases by competent and reputable men, can doubt that some cases of ectopic gestation have been conducted by this means to a favorable termination." But he concludes: "Goodell would restrict the application of electricity to those cases refusing abdominal section, or when no one can be found capable of doing the operation. I think this is the most that ought now to be said in favor of the treatment by electricity." This is certainly the view of impartial men.

During the second half of pregnancy prompt abdominal section is likewise advised. The only exception is when the fetus is dead, when sufficient delay to permit obliteration of the placental blood-vessels is advised. Whenever it is possible the fetal sac and placenta should be removed. Otherwise the placenta must be left. In this case the usual method may be employed, of leaving the umbilical cord to hang out of the abdominal wound, trusting to the drainage-tube to take care of the subsequent suppuration; or the cord may be ligated and removed close to the placenta, the sack thoroughly cleansed, and the wound closed without drainage, in the hope that the placenta may be absorbed; or this failing, a secondary operation may be done for its removal, should suppuration or septic changes occur.

A most elaborate review of the subject of placenta prævia is presented. The author evidently considers the tampon a most valuable device, and says but little concerning its dangers. But the methods of Barnes, and more especially of Hicks and of Murphy, which have revolutionized the subject, are fully given. It is interesting to find that the method of Hicks, employed in Germany in 190 cases, saved all but nine mothers. Murphy has had 38 cases, and only two maternal deaths. How pleasant a picture compared to the old mortality of 25 or 30 per cent.!

Our sensibilities are rudely shocked by the statement that the term Cæsarean section has no connection with Cæsar, but is derived from the operation—*carso matris utero.* No evidence is given in support of this statement. Parvin accepts the limitations of Winckel for the performance of Cæsarean section, viz., when the conjugate is 2.6 inches in the generally contracted pelvis, or 2.1 inches in the flat pelvis. But he adds that embryotomy in pelves approaching these limits will prove, in the hands of those not expert, often more difficult than the Cæsarean section. Operation at a selected time, towards the close of pregnancy, is advised, rather than to await labor. In discussing the

relative indications of embryotomy and Cæsarean section the author is evidently in sympathy "with the increasing number who condemn its [embryotomy] performance where the child is alive." As indications for embryotomy, other things being equal, are given: 1. When the child's life is endangered, so that the probabilities of saving it by Cæsarean section are slight; 2. When delivery of the child without mutilation is impossible, and the mother refuses section; 3. If pregnancy is at term, and delivery is possible with premature labor, embryotomy may be selected in the hope of delivering a living child in a subsequent pregnancy by inducing premature labor. Cases in which the delivery of a living child is impossible, and yet in which embryotomy is safe, are difficult for decision. The woman must decide herself. Obstruction to labor due to cancer of the uterus or vagina suggests gastro-hysterotomy, rather than embryotomy. The mortality of embryotomy in proper cases given as 0 (Winckel); six per cent. (Auvard); of Cæsarean section, 8.4 per cent. (Winckel), 25 per cent. (Auvard).

Our space prevents a further examination of this book; but these chapters cover those subjects in obstetrics in which recent advances have been made; and most faithfully has the author presented the subjects. With reference to the Cæsarean section, we could wish that emphasis had been laid on the necessity for the examination of women during pregnancy, so as to be forewarned of existing conditions. Finally it would be well for women, not only that the book should find its way into every library, but also that its precepts should be mastered by every practitioner.

MEDICINAL-KALENDER FÜR DEN PREUSSISCHEN STATT AUF DAS JAHR, 1891. In two parts. Berlin: August Hirschwald, 1891.

This exceedingly useful publication comes promptly before the beginning of the new year, and contains in addition to the form of record for physicians' work which is used in Germany, a large amount of useful literature. It contains abstracts in regard to therapeutics, diagnosis, hygiene, autopsies, and a directory of physicians in the German Empire. For other than Germans it is a very valuable means of learning a great variety of facts in regard to medical matters in the German Empire.

Literary Notes.

—Mr. George Keil, 1715 Willington Street, Philadelphia, has in preparation the *Medical and Dental Register-Directory and Intelligencer*, for the States of Pennsylvania, New Jersey and Delaware, to be ready early in 1891, and desires every physician in this region to send him the following points: Name in full, school of graduation and year, street and number, post-office and State, office hours.

The *Medical and Dental Intelligencer* will contain in a condensed form information relative to the Associations, Colleges, Hospitals, special and general Dispensaries, Homes, etc.

Its list of National and State Medical and Dental Organizations, giving list of officers, time and place of meeting, and post-office address of physicians and dentists, their office hours (in cities) school of graduation and year, will be complete to date of issue.

The work will be mailed to each physician and dentist whose name appears in its pages.

Special Article.

KOCH'S REMEDY FOR TUBERCULOSIS.

A RESUMÉ OF ITS HISTORY.

[*Continued from Vol. lxiii, page 738.*]

The *Glasgow Medical Journal* for December contains a letter from Dr. W. Gordon, written from Berlin, November 18, and giving the views of Prof. Liebreich in regard to the Koch remedy. These may be summarized as follows: Prof. Liebreich thinks the fluid is certainly efficient as a test of the presence of tuberculosis and in the treatment of lupus—although he claims only improvement and "dare not" say cure. For phthisis he believes in "general improvement in some cases," but "no cure yet."

In a lecture before the Society of Physicians of the Charité Hospital in Berlin, Nov. 20, 1890 (*Berliner Klinische Wochenschrift*, Dec. 1, 1890), Köhler showed a number of patients in whom he had used the lymph for diagnostic and therapeutic purposes. In regard to the former, he claimed that persons with tuberculosis reveal the fact by a marked local reaction, while many cases of other surgical lesions present no such reaction. As to the former he showed a case of superficial lupus which he said was fully healed. He concluded with the statement that Koch's discovery is a "triumph of science."

In the *Berliner Klinische Wochenschrift*, December 8, Leyden gives a most interesting account of his experiences with the lymph from November 20 to November 27, covering 46 patients and 136 injections. His paper is a model of scientific fairness and discernment. He made an especially and very important point of the indications of the tuberculous character of serous pleurisy which were furnished by the effects of the lymph under his observation. As to the diagnostic value of the symptoms of reaction, he says that some patients who presented the reaction were absolutely free from suspicion of tuberculosis—as in cases of scarlatina and erysipelas. He concludes by saying his impression is that the "lymph" is an extraordinary medicament, but does not venture to claim that it is a trustworthy means of diagnosis. As to its curative properties he says he cannot express an opinion.

As to the changes in the bacilli, he says they cannot be regarded as a characteristic effect of the lymph because like changes are observed at times in untreated cases.

The first physician in America to administer the Koch lymph was Dr. J. P. C. Foster, of New Haven, Conn., who on December 3 used it on a patient with consumption.

On December 9 Dr. V. P. Gibney, of New York, used the lymph for Dr. Allan McLean Hamilton, at the N. Y. Hospital for Ruptured and Crippled.

On December 10 Dr. William H. Bennett, of Philadelphia, began using the lymph.

On December 10 Dr. Francis S. Kinnicut used it at St. Luke's Hospital, New York.

On December 12 Dr. Osler began using it at the Johns Hopkins Hospital.

On December 13 the University of Pennsylvania issued as a special number of the *University Medical Magazine*, a bulletin summarizing the facts so far published in regard to the Koch remedy and describing the method determined upon for its systematic study by a commission of the University.

On December 17 the lymph was first used at the University of Pennsylvania by Dr. J. William White and Dr. J. H. Musser, and at the Jefferson Medical College by Dr. F. P. Henry, Dr. William M. Angney and Dr. J. Solis-Cohen. The reports from the latter institution indicate nothing of special importance—reaction and hope on the part of the patient are recorded. At the University the effects of the lymph are being carefully and thoroughly investigated, and no reports are to be made public until enough observations have been made to warrant them.

[On December 29 Dr. Cohen informs the REPORTER that his patient at the Jefferson Medical College, a young man æt. 26, is an instance of advanced *tuberculosis pulmonum et laryngis*, with softening in the apex of the right lung and with nodular infiltrations upon the vocal bands and in the posterior wall of the larynx. He had been under treatment for two months, with large doses of creasote internally, and topical applications of first lactic acid, then menthol, and subsequently iodoform, under which he was progressing favorably; the night-sweats having ceased, nutrition having improved and the temperature having become practically normal. Tubercle bacilli, however, remained very abundant in the sputa. When the Koch treatment was instituted, the former treatment was suspended. The constitutional reaction was moderate under the first injection, and the larynx underwent marked congestion without any signs of œdema. After the second injection, the constitutional reaction was greater; and the inflammatory manifestations became more marked upon the vocal bands and in the posterior wall of the larynx.

After the third injection, the reaction was a little less than after the second, but this was soon followed by an absolute reduction of temperature below normal, and by a commencement of ulceration in the posterior laryngeal wall, so that it was decided to suspend the injections and watch the local manifestations. While the patient considers himself much better, Dr. Cohen does not consider his condition as good as it was when the injections were begun, and, unless on December 29, a marked improvement was found upon the condition noted on Saturday, the treatment with creasote and iodoform was to be resumed.]

In the *Berliner Klinische Wochenschrift*, December 10, 1890, there are instructive papers by Senator, Henoch, Litten, Turban and Ewald. Senator calls attention to the fact that he has now found the reaction did not correspond in the earliness of its onset, its amount or its continuance to the severity or extent of the tuberculous process. He says this reaction is exactly similar to what is known as febricula or ephemeral fever. He found evidences of depression of the force of the heart during its reaction. On account of the explanation of the *modus operandi* of the "lymph"—necrosis of the tuberculous tissue—he thinks the remedy especially valuable for tuberculosis of open passages like the pharynx and larynx, the intestines, and the urinary tract. He has seen it do good in a number of cases.

Ewald's paper is of very great interest as a thorough and systematic study of about one hundred cases in which the lymph was administered. The general conclusion may be stated as that it is useful for diagnostic purposes and as a remedy in the initial stages of tuberculosis of the lungs as well as in pleurisy.

The *Deutsche Medicinische Wochenschrift*, December 11, contains an address by Helferich, delivered before the Greifswald Medical Society on December 6, in which a full description is given of the effects produced by Koch's remedy in a number of cases of lupus and tuberculosis of the bones and

joints. It concludes with the statement that, in view of his experience, we may have "not the hope but the certainty that Koch's remedy in diagnostic and therapeutic relations marks an epoch-making advance."

In the same journal, Wolff, Director of Dr. Brehmer's Sanitarium at Görbersdorf, gives his experience of the reaction of phthisical patients after receiving injections of Koch's remedy. He found that advanced and grave cases furnished more marked reaction after minimal doses and that incipient and light cases sometimes reacted only after a repetition of the first dose. He describes some cases in which the patients were decidedly worse after receiving the injection; but he says the lymph did good service at Görbersdorf as an aid to diagnosis.

Arning, of Hamburg, in the same journal reports the use of Koch's remedy in two cases of leprosy: one showed no reaction whatever; the other, under the care of Dr. Engel-Reimers had a marked reaction; but this was general and not such at the points of leprous manifestation as is reported in regard to lupus.

Before the Medical Society of Hamburg, Schede, on December 2, reported good early results with the remedy in cases of lupus, tuberculosis of the joints. Maes, of Hamburg, reported good early results in lupus cases. Kast expressed a conservative opinion as to the therapeutic value of Koch's remedy; but spoke favorably of it as a means of diagnosis.

In the same journal in a report of a lecture by Paul Guttmann in which he described the manner of administering Koch's remedy and showed two young women as cured, who had had pronounced symptoms of tuberculous catarrh of the apex of the lung.

The *British Medical Journal*, December 13, contains a lecture delivered by Sir Joseph Lister at Kings College, December 3, in which he not only expressed great confidence in the diagnostic and therapeutic value of Koch's lymph, but also intimated that before many weeks the world might be startled by the disclosure by Koch of an "inorganic chemical substance as easily obtained as any article in the materia medica" which he saw cut short in animals the otherwise deadly course of "two of the most virulent infective diseases to which man is liable."

In the same journal in an address by Dr. Yeo describing his observations at Berlin; as to the curative value of the lymph he says: "Here, however, as well as elsewhere, it was scarcely possible, so short a time had the patients been under treatment, to observe that any actual curative changes had taken place. But it was exceedingly interesting and important to note the action of Koch's injections in cases in different stages of this disease."

As bearing on its diagnostic value he says he saw a case of chronic phthisis that had been in Davos for two years, and failed to react to doses of 3, 5, and 8 milligrams respectively; and there were one or two more case of undoubted chronic phthisis with bacilli in the sputum that had not reacted to the injections that had been made up to the time of his last visit. Another case in Professor Ewald's clinic, that yielded no marked reaction after injection of ordinary doses, was that of a highly neurotic young man, with tubercle bacilli in the expectoration, but no well-marked pulmonary physical signs. This was also the case with a gentleman who was in a private sanatorium in Berlin, and whom Dr. Yeo had seen in London in September, 1887. In this case there were evidences of a good deal of pleural thickening, and probably extensive fibroid changes in the left lung.

Nevertheless, he says: "Of one thing there can be no doubt; we have in this fluid of Koch's an agent which exerts a specific action on tuberculous processes. A minute quantity, such as from 1 to 10 milligrammes, which produces no effect on non-tuberculous persons, gives rise to the remarkable effects with which we are now familiar in persons affected with tuberculosis." . . .

Again he asks: "Have we here a cure for tuberculosis? and a cure for pulmonary consumption?" and adds: "I put the two questions separately because I do not consider them identical. . . . In advanced pulmonary consumption we have morbid changes to deal with other than those originally started by the tubercle bacillus, and even if we could destroy every bacillus in the lung as well as the products of their agency, we should in many instances still have to deal with a hopelessly damaged organ. And, even although Koch's treatment may be essential to the arrest of the disease in less advanced cases, hygienic and medicinal measures will be as needful as ever to guide the patient to a permanent cure. . . . I am disposed, from what I have already seen, to conclude that Koch has not been deceived in the observations on the

human subject which he has already made, and that his published conclusions will, in the main, be found just and accurate."

In the same journal, Dr. R. W. Philip, of Edinburgh, a special student of consumption, after a careful investigation of the subject in Berlin and in his own hospital practice says: "With regard to final results in these cases, especially in phthisis, it is premature to say much. In very advanced cases, of which I had the opportunity of studying about a dozen, I cannot say that I was satisfied of any definite improvement. The *post-mortem* results of the two or three fatal cases, so far as they have been communicated, point, however, to a local influence having been exerted on the affected organs.

"In less advanced cases, but still cases where, prior to the special treatment, physical examination revealed considerable areas of percussion dulness and abundant crepitations and when the patient suffered from loss of flesh, hemoptysis, night-sweats, and anorexia, the report must be more hopeful.

"In a considerable proportion of these I think we may safely admit that very definite amelioration can be effected. I observed a number of cases where night-sweats had disappeared, where the cough was practically gone, where there was a diminution or cessation of expectoration, and where the patient's subjective condition was better, and a few where there was a gain of several pounds in weight. In very few cases was I able to trace important improvement in the physical signs; but the time was too short for this, and no case has, so far as I was able to learn, been released from treatment as cured. Still I think, pending further observation, we are bound to fall back on the authority of Koch, who states categorically that within four to six weeks patients under treatment in the first stage of phthisis were all freed from every symptom of disease, and might be pronounced cured."

Likewise in the same journal there is a report of cases observed by Dr. William Hunter in Berlin, and treated by Mr. Watson Cheyne and by Dr. Heron in London. Reports of use of fluid at Manchester, Dublin, Glasgow are made and it is said that twenty-three cases were under treatment at Edinburgh, and that the fluid has been tested at the Brompton Hospital. It has also been used for the first time in Italy, by Prof. Bacelli, on November 29.

Notes and Comments.

Forty-five Days' Fast.

Succi, the Italian faster, who began a fast of 45 days in New York on November 5, ended his fast at 8.23 P. M., December 20, 1890. Other fasters have gone forty days without food, but they were so weak that they could not sit up. Dr. Tanner could not sit up after the tenth day, and could not write his name after the fifteenth day, but Succi has scorned the idea of weakening all through the weary weeks. On his fifteenth day he rode seven miles on horseback, and has exercised every day since. During his fast Succi drank freely of water, and took small quantities of a liquid which he calls an elixir and which is supposed to contain morphia.

At 6 P. M., December 20, he was examined and his weight was found to be 104¾ pounds; on November 5 it was 147¼ pounds—a loss of 42½ pounds, or less than a pound a day. His temperature was 98.2; pulse, 62; respiration, 19; general condition weak; tongue clear, moist and steady. The bulletin was signed by the thirteen physicians who have watched during the fast. The worst attack of gastric trouble that he had during his fast occurred on the last day, during which his pain was so acute that it was feared he would collapse; but his will power carried him through. From 5 P. M. until he took his first cup of cocoa, at 8.20, his pain continued to be more or less acute. It was evident in many ways—by the distortions of his face, which was horribly shrunken; by his frequent change of position on the lounge upon which he was reclining; by the nervous twitchings of his wasted hands; by the restless glare of his deep-sunken eyes, and in various other ways.

When the cocoa was prepared, shortly after 8 o'clock, Succi got off the lounge and staggered to the table where the nourishing diet was placed. The spectacle he presented was pitiable. He looked like a skeleton.

The next day Succi arose from sleep after a long slumber, which he fell into shortly after his feat was ended, and an elaborate meal was placed before him. He ate with extraordinary relish.

Following is the ménu: Anchovies, with butter; chicken soup, with rice; fried smelts, fried calves' brains, quail on toast, cocoa pudding, fruit, confections, ice-cream, coffee; one-half pint Rorals Extra; one-half

pint Grand Sec. He occupied two hours in consuming the food placed before him. He never faltered, but ate with zest.

Extirpation of the Bladder.

At the meeting of the Tenth International Medical Congress, at Berlin, in August last, Pawlik, of Prague, read a paper on extirpation of the bladder, which appears, in the form of an abstract, in the *Mercredi Médical*, November 5, 1890. It seems that the patient upon whom the operation was performed had persistent hematuria, which was ascertained, by catheterization of the ureters, to come from above the bladder. When the urethra was dilated, digital exploration and examination through the endoscope disclosed the presence of a polyp having a slender pedicle. The polyp was removed with the thermo-cautery through an opening from the vagina into the bladder, the fistula being subsequently closed. Complete recovery ensued. The woman left the hospital July 28, 1888.

One year later, in July, 1889, the patient returned. For eight months after the operation she had been in very good health, then hematuria reappeared and persisted. By endoscopic examination a papillomatous mass was discovered, attached over a large part of the surface of the bladder; the growth proved upon microscopic examination to be malignant. A radical operation was decided upon. The one adopted consisted in separating the ureters from the bladder and fastening them in the anterior vaginal wall, then excising the bladder and creating a new bladder by utilizing the remaining portions of the urethra and vagina.

The first operation was performed August 3, 1889. After the introduction of a metallic catheter into each ureter, the woman was placed in the knee-chest position; the vagina was then incised, in the direction of each ureter, for a distance of three-fourths of an inch, the ureter was dissected up and an incision of one-third of an inch was made in its posterior wall. Below this incision, the ureter was tied, and then separated at its vesical end from the bladder, the edges of the orifice of the ureter being then sutured to the opening into the vagina. Extirpation of the bladder was performed August 27, at a second operation. The bl[illegible] and, without injuring the peritoneum, the bladder, previously filled with an emulsion of iodoform so as to make it easily recognizable, was dissected to the internal orifice of the urethra. The bladder was then emptied and the sub-vesical space was tamponed with iodoform gauze, to prevent any hemorrhage. A transverse incision was now made immediately over the prominence made by the urethra in the anterior vaginal wall; this incision was made sufficiently large and the bladder was brought down through it into the vagina and excised at the internal urethral orifice. At this point in the operation, the patient went into collapse, but recovered on receiving a subcutaneous injection of nine and one-half fluid ounces of warm physiological salt solution. The anterior vaginal wall was sutured to the anterior border of the urethral wound, while the posterior border of this as well as a circular freshening of the entrance of the vagina were utilized to close up the vulvar outlet. Before trying the sutures, an elastic catheter was introduced into each ureter. The abdominal wound was closed down to its inferior angle, from which strands of iodoform gauze passed. The attempted closure of the vagina (colpocleisis) failed, and a fistula formed at the junction of the anterior vaginal wall with the anterior border of the urethral wound. Another attempt at colpocleisis, made June 20, 1890, also failed. On July 18, Pawlik performed sagittal colpocleisis, which succeeded, save for the persistance of a small fistula immediately behind the urethra. When in bed the patient retained her urine a long time; but when she rose, the urine dribbled from the fistula. She is fully aware when the new bladder, which has a capacity of about thirteen fluid ounces, is distended with urine; and she is able to evacuate it voluntarily, by the action of the perineal muscles. There is no doubt, Pawlik thinks, that if the fistula closes, the artificial bladder will possess sufficient retentive power. However that may be, it is a satisfactory result already, that the patient, who for a year was exposed to imminent death, can endure a great deal of fatigue.

Infant Feeding.

In an article in the *Northwestern Lancet*, November 1, 1890, Dr. A. H. Tufts says:

Regularity of time of feeding should be carefully observed. The infant stomach needs periods of rest just as much as the stomach of an adult. The habit of throw-

ing a bottle full of milk, accompanied by the deadly tube, into the crib or into the carriage for the infant to pull at while being trundled about in the hot sun, giving him the opportunity to gorge his stomach at any and all times, is enough to kill a robust man, to say nothing of a tender infant. Under one month of age, once in two hours is often enough to feed the healthy baby, the time to be gradually increased until at six months it is fed once in three or four hours from six A. M. until ten P. M. From ten P. M. to six or seven A. M. the child should sleep through, without feeding. We need to constantly warn and caution the over-anxious mother against overfeeding, or all our painstaking and care may be counterbalanced.

Too often the infant is given food when it needs and wants water instead. Dr. Tufts says he has often known of infants several weeks old who had not been given a spoonful of water, and whose parents seemed surprised when told the little one needed it as much as any one. Sometimes the mother says it will not take cold water; when it may be given warm. If babies were earlier taught the habit of taking freely of water he believes constipation would be less frequent among them.

Symptoms of overfeeding are restlessness, vomiting and undigested food in the feces. The latter used to be always called undigested curds or casein. Now comes one who says this is undigested fat, and proves his statement by saying this material is soluble in ether and alcohol, while casein is not. This, if true, must make quite a difference in our regulating the proportions of milk and cream.

[In this connection we quote from the *Medical Record*, November 15, 1890, thus: Dr. Macleod says mother's milk is always considered by the people of India as insufficient to sustain infant life, and various kinds of milk or other artificial kinds of food are suggested by wise friends to replace it. Cow's milk is generally used as infant food by all middle-class people of Bengal. Donkey's milk is largely consumed in rich families. The Mohammedans, whether rich or poor, prefer goat's milk to any other of its kind; while sheep's milk is considered to be the best article of food by the people of the Northwestern Provinces. Instances have been known where mothers with full breasts and an abundant supply of milk have kept their offspring entirely upon artificial food and thus invoked disease.—ED. REPORTER.]

Mayer's Ointment.

In a recent issue of the *Pharmaceutical Era* Professor J. U. Lloyd goes into the origin and history of Mayer's ointment, a favorite with eclectic practitioners. Probably John Quincy's "Common Plaster" was a forerunner to it, but it appears certain that some forty years ago a domestic ointment obtained considerable reputation among certain citizens of Cincinnati, and became known under the name "Mayer's Ointment." This ointment was supplied in small tin boxes, and was prepared by a Mrs. Mayer, who exercised great secrecy in the purchase of the ingredients, buying them severally from different druggists, a few from each, in order that no person should learn the entire composition of the salve. A formula for an ointment similar to this was given to Professor John King by Mr. Joseph P. Mayer, of Cincinnati, and it was introduced into his "Eclectic Dispensatory." The formula is as follows:—To olive oil, 2½ lbs., add white turpentine, ½ lb.; beeswax, unsalted butter, of each 4 oz.: melt them together and heat to nearly the boiling point. Then add gradually red lead 1 lb. and stir constantly until the mixture becomes black or brown; then remove from the fire, and when it has become somewhat cool, add to it a mixture of honey, 12 oz., and powdered camphor, ½ lb. Lard may be used instead of butter.—*Chemist and Druggist*, November 8, 1890.

Lanolin Milk.

Paschkis recommends lanolin milk as a most excellent cosmetic, especially for skins poor in fat. It is valuable also as a powder base, giving the skin an almost invisible covering of fatty material, which takes and holds cosmetic powders most admirably. It is prepared as follows (approximately):

Rub up 75 grains of lanolin with about a fluid ounce of water, warming gently. To this mixture add 4 grams neutral soap dissolved in an ounce of water; rub up again, and immediately add sufficient warm water to make about 12 fluid ounces and agitate thoroughly. If desirable, 15 grains of tincture of benzoin or borax dissolved in a little warm water may be added. The mixture must be strained, because, even when most carefully made, small lumps of uncombined lanolin will remain suspended in it.

Condensed Milk for Emulsions.

It is said that nothing equals condensed milk for making emulsions, and according to the *Formulary*, the expense is not relatively great. To make a pint of 50 per cent. emulsion of cod-liver oil, take of

Cod-liver oil	8 fl. ounces.
Condensed milk	3 fl. ounces.
Glycerin or syrup	3 fl. ounces.
Water	2 fl. ounces.

Add of a flavoring oil, such as bitter almond, 10 drops, or wintergreen, 15 drops.

Rub the condensed milk round in a dry mortar, and gradually add the cod-liver oil, working it in as is customary in making emulsions. When thoroughly incorporated add the glycerin, and lastly the water and flavoring extract.

Malaria in Birds.

Danilewsky has recently written to Dr. Dock, of Galveston, Texas, that he has seen acute malaria in birds, with rosette forms of the parasites, confirming his earlier view of the similarity [he says in parenthesis, "identity?"] of the organisms.

NEWS.

—Dr. Matthew Woods has removed to 1307 South Broad Street, Philadelphia.

—Dr. L. Webster Fox has just been appointed ophthalmic expert to the Board of Pension Examiners of the Philadelphia district.

—Dr. B. A. Randall has been elected Clinical Professor of Otology, at the University of Pennsylvania, succeeding Dr. George Strawbridge, resigned.

—The steamer San Juan, at San Francisco December 4 from Panama, reported that the cholera was making terrible ravages in Guatemala. More than 12,000 cases were reported in the State and 1,200 deaths had occurred in the city of Guatemala in seven weeks.

—The prize offered by the Medical Society of the County of New York for the year 1890 has been awarded to Dr. David Cerna, assistant in physiology, University of Pennsylvania, for his essay entitled, "A Physiological and Therapeutical Study of Hydrastis Canadensis."

—Dr. Albert P. Brubaker, of Philadelphia, was, on December 12, chosen by the Committee of the Trustees of the Jefferson Medical College to fill, for the remainder of the college term, the chair of Materia Medica, General Therapeutics and Hygiene, lately occupied by Professor Roberts Bartholow.

—Word is received from Nicaragua that a new disease has appeared there and has caused several deaths. The victims are seized with severe pains in the stomach. The pain is followed by dysentery and if prompt measures are not taken the sufferer dies within four hours. Dr. Espenosa, of that place, considers the disease a precursor of cholera.

—It is stated in the newspapers that a San Francisco physician has cured a number of cases of cancer, and that three pronounced cases from the New York Cancer Hospital are now on the way to San Francisco in charge of a prominent surgeon from New York, to be operated upon. The result will perhaps determine whether the treatment shall be introduced into the New York Hospital.

—The Senate, on December 30, confirmed the nomination of Dr. Charles Sutherland to be Surgeon-General of the Army. Dr. Sutherland is the ranking surgeon of the medical corps, and in making this promotion the President followed the rule of seniority. Dr. Sutherland is a native of Pennsylvania, and was appointed to the army from this State in 1852. He has a good record for service in the army and stands high in his profession and with officers of the line and staff of the army. He has four years to serve from May next before reaching the age for compulsory retirement.

—Dr. John Davis, one of the oldest physicians of Cincinnati, died suddenly on Christmas night at his home. He had been at Christmas dinner with his wife and a few friends, and while sitting in his library, was attacked with a violent fit of coughing. In half an hour he was dead. Dr. Davis was nearly 70 years old. He was an intimate friend of ex-President Hayes, and often entertained him and Mrs. Hayes, on their visits to Cincinnati. Dr. Davis was, at the time of his death, President of the Union Central Life Insurance Company, and also President of the Law and Order League of Cincinnati, in whose interest he was earnest and active.

℞ Baker's Cod Liver Oil with Extract of Malt.

A PREPARATION THAT HAS GIVEN GREATER SATISFACTION THAN ANY IN OUR EXPERIENCE.

NO EXPLANATION IS NEEDED AS TO CONSTITUENTS.- IT IS SIMPLY OUR FINEST NORWEGIAN C.L. OIL. WITH THE EXTRACT OF MALTED BARLEY (EVAPORATED IN VACUO) RICH IN DIASTASE & CAPABLE OF CONVERTING MANY TIMES ITS OWN WEIGHT OF DRY STARCH INTO MALTOSE.

Malt aids Digestion and is nutritious.
Malt covers taste of oil.
Malt has emulsifying properties.

HAVE YOU NOT A CASE IN WHICH YOU WILL USE IT? THE RESULT WILL CAUSE YOU TO THANK US FOR THE SUGGESTION.

Jno. C. Baker & Co.
Philada.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{10}$ gr.), Atropiæ Sulph. ($\frac{1}{500}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. ($\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{10}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

CLINICAL LECTURES.

ACUTE PARENCHYMATOUS NEPHRITIS FOLLOWING WHOOPING-COUGH.—CHRONIC PARENCHYMATOUS NEPHRITIS MISTAKEN FOR CHLOROSIS.

BY W. C. HOLLOPETER, M. D.,

CLINICAL LECTURER ON DISEASES OF CHILDREN IN MEDICO-CHIRURGICAL COLLEGE, PHILADELPHIA.

Nephritis after Whooping-Cough.

Gentlemen: You will recall this case as the one I had before you a few weeks ago, when I was illustrating the sequelæ of whooping-cough. The child is but three years old. The mother held the belief, so common among many of the laity, that the doctor can be of but little use in relieving or curing whooping-cough. Hence the little boy has been permitted to encounter a stormy disease unaided, a storm so violent that nearly every organ in his body has become involved in consequence.

You will recall the fact that, when I first presented him to you a few weeks ago, he was very weak and miserable, besides showing a marked anemic condition, the result of his recent severe illness. He has a perforated membrana tympani, and, as the natural accompaniment, a purulent otorrhœa; also an oblique inguinal hernia of the worst possible character—the abdominal rings have been so far dilated that the omentum has followed the spermatic cord down into the scrotum, and by long-continued friction incident to the cough has formed inflammatory adhesions of so firm a character as to preclude, at least for the present, any hope of reduction. The chain of cervical lymphatics is also enormously enlarged, extending from the mastoid process down to and below the clavicle, and entering the mediastinum. This enlargement of the bronchial glands has induced a constant cough by pressure on the tubes, and the condition was for a time very suggestive of bronchopneumonia. The cough had ceased, however, and the child was apparently improving. Two weeks ago the cough reappearing, grew rapidly worse, and, in conjunction with it, the child commenced to vomit, but not very frequently at first. He was irritable, slightly feverish, and had lost his appetite. These symptoms continued for a few days; fever of not an unusual type was present for one day; the child was restless and very irritable, vomiting constantly for one whole day, and with his sleep much broken. At the expiration of the first forty-eight hours, the fever, vomiting and persistent cough diminished, the urine was now noticed to be lessened in quantity; and by the third day, when the fever and vomiting had entirely ceased, the urine was completely suppressed. The face was now ashy pale; the eyes were sunken and dull, and the lids appeared full and swollen. About this time it was noticed that the most dependent portions of the body commenced to show a dropsical accumulation. In this sluggish, stupid—I might say comatose—condition, the little fellow remained for two days, and during all that time he did not void one-half an ounce of urine. A blanket wrung out of hot water was used to envelop him, while hot poultices were placed over the back, and sinapism to the feet and legs. Milk and water was his only food. Small doses of calomel, frequently repeated, were exhibited, until he had a free action of the bowels. This acted as a derivative to his head, and as a vicarious means of unloading the renal pressure. One drachm of Rochelle salts was also exhibited in hot water for the same purpose. Slowly the kidneys resumed their function. At first the urine was scanty, very dark and coffee-colored, smoky from the blood it contained; but as the quantity in-

creased, the color became lighter; the dull, shapeless face assumed a more intelligent expression; and the sluggish condition of the boy became less marked. The outlines of the eyes and nose grew more natural; and with the gradual dawn of intelligent expression there was a subsidence of all the nervous symptoms; and thus our little patient had at last passed through the acute stage of parenchymatous nephritis.

Acute nephritis, called parenchymatous or desquamative nephritis, you will find is an almost constant sequela of scarlet fever. It also frequently follows measles, diphtheria, small-pox, and occasionally typhoid fever; but it is extremely rare to find it following whooping-cough. I have been unable to find any mention of in the text-books. In the light of modern investigation relative to the acute infectious diseases of children, it has been proven that in most, if not in all of them, systemic infection occurs through ptomaines, or the poisonous chemical agents which are produced by the action of microbes in the system, which are the original specific principle.

The symptoms of acute nephritis differ according to the causes that produce it. If it follows the specific diseases that I have mentioned, its onset is much obscured by the previous indisposition of the patient, as was illustrated in our present case. If it follows scarlet fever, the convalescence is of necessity greatly retarded. We scarcely know why the child has been so poorly, until perhaps we make some inquiry concerning its urine, when we notice that it is suppressed or scanty, or, perhaps notice the commencing dropsy. The child may cough—in fact, this child had scarcely got over the habit of coughing which so frequently follows pertussis, when the fever, the cough and the suppression of urine announced the kidney complication. You will recall the physiological relation that the skin and kidneys bear to each other. You can understand how we may have acute nephritis ushered in. When the child is perspiring at play, sits down to rest, and is subjected to a draft, or it takes a cold bath and a sudden suppression of the urinary secretion is the result, the whole burden of the excrementitious material is thrown on the kidneys; congestion and inflammatory action is sure to follow.

An analysis of this child's urine as it now is gives us the following result: Quantity passed during the twenty-four hours, ten fluid ounces; color, dark brown; odor, strong; albumin, 10 per cent. by volume; blood present in small quantity; a small quantity of mucus. Microscopical examination reveals epithelium, mucus, blood-fibrin and hyaline casts.

Nephritis Mistaken for Chlorosis.

Our second case illustrates a train of symptoms that we rarely meet with among children. This child, that I now bring before you, has been ill for two years. Her history is briefly as follows.

Minnie H., 15 years old; father and mother both living and in fair health. They have lost no children, and the family history is good. Minnie has not been sick since her third year, when she had measles. This disease, however, was not attended by any of the usual complications, such as acute nephritis, or ear trouble, or enlarged glands. She made a good recovery, so far as her parents could judge. Following measles, the girl has had a long period of perfect health, up to her thirteenth year. She was at this time full of spirits and life, enjoying play, and seeming as natural as is usual for a girl of her age. She had a fair color, although she was never of a rosy complexion. Her appetite was good, although she did not enjoy her food as a child of her age should. About two years ago she was noticed to grow less active; her disposition becoming more quiet and somewhat sluggish; her appetite, at the same time, grew indifferent; her desire for companionship grew less; in fact, she became irritable in temper and morose in habit. She avoided companionship. When her girl friends would call on her, their presence seemed to excite her, rather than to give her pleasure. She seemed to be better content to be alone than in their company. She is a day dreamer. She will now sit all day long gazing out of the window into vacancy; and if you ask her what she is looking at, she will scarcely be able to tell you. Her temper has also changed, she being easily annoyed. She will grow angry and excited if opposed, or cry, if scolded. Any unusual sight on the street, such as a drunken man, or fighting dogs, will greatly excite her and render her sleep troubled and broken. She has been in this stupid condition for nearly two years, it is slowly but surely becoming more marked.

During this interval she has been treated for malaria, bronchial catarrh, and finally for amenorrhœa.

I saw this girl for the first time one week

ago, when I elicited the history that you have just heard. I was inclined to make a diagnosis of chlorosis—a very common complication of puberty. There was a heavy, fetid odor about the girl's breath or person, that suggested a purulent discharge, either from the ear or throat. Careful examination revealed neither ear nor throat trouble. She was soft, white, anemic, yet not dropsical. She appeared to be stupid, as she sat in the chair and answered my questions in monosyllables. I could discover no dropsy. The heart was greatly accelerated on examination, as would be natural in anemia. I thought it might have been increased somewhat by my examination. The girl is well developed for her age; the mammary glands are fully enlarged and all the evidences of maturation have been reached. The mother tells me she has never seen her monthly expression. Thinking I had simply a case of chlorosis, or amenorrhœa, I prescribed a pill ferri carbonates and arsenic. The mother informed me at her first visit that she had repeatedly asked the doctor about the girl's water, saying it was scanty, and that she passed it with difficulty and that it was offensive. The day after her first visit, I was hastily summoned to her bedside, when I found the following condition. The girl was unable to lie down, but maintained a semi-recumbent position. The heart's action was intensely accelerated, running at the rate of 140 beats a minute. Dyspnœa was painfully great. She was unable to retain a recumbent position at all, and could find comfort only in leaning forward and supporting herself on a chair. She complained also of sharp pain in the region of the heart. On inquiry I found the urine entirely suppressed. I ordered a counter-irritation over the heart, and, as she had a temperature of 103° and thinking it was a case of pleurisy, I gave her three grains of acetanilid and one-fourth grain of calomel every hour. At the expiration of six hours I was again summoned. Her symptoms were not improved; indeed she was in a still more critical condition. The pulse was so rapid that it was scarcely perceptible; the dyspnœa was greatly increased; the position that she now assumed was almost a hanging one, forward; the stabbing, lancinating pains in the region of the heart were intensified; her cough was dry, short and constant. At this time I ordered a fly-blister over the region of the heart, and also made inquiry in regard to the urinary secretion. The mother informed me that it was still suppressed. Eight hours after the second visit I saw her again, and found the symptoms still exaggerated; her lips were blue; her face was blanched, approaching lividity; the muscles of the chest were laboring frantically; the radials were imperceptible; the pain was still intense; the cough was short and dry. She was in a state of collapse. A short time after this some relief was apparently manifested in the expectoration that she coughed out, as it was tinged with blood. This increased until the mucus expectorated was about one-half blood. The bloody expectoration, light and frothy, continued for fully eight or ten hours, when it gradually subsided, and with it all the distressing symptoms.

Without going further into details, we have here, gentlemen, a case of pericarditis, left pleurisy and acute bronchitis as a result of chronic parencymatous nephritis. Chronic parenchymatous nephritis rarely follows the acute form. It is also a disease of youth and is seldom found after thirty-five years of age. It is usually induced by some constitutional defect or depressing surroundings. These symptoms occurred in the order I have named, simply by extension, and gradually subsided. We obtained a urinary analysis at this time, and found that the girl was passing, on an average, about three or four ounces of urine per day. This continued for a few days, when, under active treatment, it gradually rose until twelve ounces had been reached. You will remember that from forty to fifty-five ounces is the usual average in health. A careful analysis shows the following results:

Physical Characteristics. — Quantity in 24 hours at this time twelve fluid ounces; color, pale; condition, sedimentary; reaction, neutral; specific gravity, 1.014; total solids, 10.87 grams.

Normal Ingredients—Sulphates, normal; chlorides, normal; indican, normal; earthy phosphates, diminished; urea, diminished; alkaline phosphate, diminished; uric acid, increased.

Abnormal Constituents. — Albumin, in amount about half the volume; no sugar.

Sediment.—Crystals of urates, few phosphates; granular and fatty casts.

The diagnosis in a child of this age between chronic parenchymatous nephritis and chlorosis or ordinary anemia presents a very difficult problem. Barthow says that "girls at the age of puberty are generally

subject to chlorosis. They may be with or without disorders of menstruation. The affected person experiences a change of her feelings, becomes morose or despondent and capricious, vibrates from the extreme of high spirits to corresponding depression; but low spirits is the habitual state of the largest number."

You will notice how closely this definition of chlorosis has been followed out in the patient before you. At the present time, however, all the chest symptoms have subsided, except a little bronchial catarrh and pleuritic friction sounds. She is still pale as you see her, and still somewhat swollen; her face is expressionless and shapeless. The heart is still beating at the rate of 120 or 130, and the urine still remains decidedly below the normal in quantity, and is loaded with albumin.

A hint is desirable here in regard to the treatment. After the counter-irritations and the poultices, and the sweating, to tide over the acute spell, infusion of digitalis and strychnia were exhibited. Digitalis is theoretically contra-indicated, as you know, by reason of undue pressure exerted on the renal structure. I withdrew it, and gave her Basham's mixture, combined with strychnia; but at the expiration of twenty-four hours I found this would not relieve her, as she complained of pain and numbness, and the urine seemed to be lessened in amount. She has therefore resumed her infusion of digitalis and strychnia; and, by careful attention to clothing and exercise, and by limiting her food to milk, we hope to improve her general condition.

WHOOPING-COUGH.—GREEN STOOLS OF CHILDHOOD.[1]

BY H. A. HARE, M. D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN IN THE UNIVERSITY OF PENNSYLVANIA.

Gentlemen: The first case I wish to show you to-day is one of whooping-cough. Whooping-cough is the third most important disease of childhood. According to statistics taken among the children of England, the greatest mortality is found to be due to scarlet fever, the second greatest to measles, and the third to whooping-cough, while in London pertussis is second in importance. But little is known of the etiology of this disease, further than that it is very probably due to some micro-organism which has not yet been isolated. A number of micro-organisms have been claimed to be the causative agent, but some who have investigated the matter pronounce them in no way different from bacteria found elsewhere. We know, however, that whooping-cough is a distinctly contagious disease. If whooping-cough breaks out in a neighborhood, all the children of that neighborhood will probably be affected. It runs a course of from six to eight weeks, and if the child is under two years of age the prognosis is unfavorable. We know, also, that the prognosis depends upon the severity of the attack and the strength of the child. The pathological appearances of the air passages macroscopically do not differ from those of ordinary bronchitis.

Upon listening over the chest, we hear râles, more especially at the base posteriorly, and after a whoop these râles are increased in intensity and are more diffused, showing that some mucus has been dislodged in the bronchial tubes by the effort of coughing. Some cases of whooping-cough whoop every five or ten minutes, or even oftener, and in some children there seems to be a constant convulsive condition of the whole respiratory tract. In other cases the whoop occurs but once in twenty-four or forty-eight hours. In treating these cases of whooping-cough it is often essential that the child be pampered to some extent, since anything which tends to cause it to cry will bring on a spell, and the child will become exhausted. When once you hear the cough of this disease you can never mistake it for anything else. There are two varieties of cough; in the first place there is the whoop which gives the name to the disease, and in the second place there is a dry, hacking cough which precedes the whoop. It is by the latter that we make our diagnosis in fifty per cent. of the cases we see, which are brought to us in the early stage of the disease. This primary cough, which comes on days before the whoop appears, is as characteristic as is the whoop. It occurs in from fifteen to twenty short respiratory movements, and in the advanced stage of the disease is followed by the characteristic whoop. We distinguish this primary cough from the cough of the first stage of bronchitis, by the fact that the latter is harsher and more rasping than is the

[1] Delivered at the University Hospital.

whooping-cough. This first period of the disease lasts for an indefinite time, but in time a slight increase in the inspiratory sound following the cough is heard, which gradually develops into the characteristic whoop which can be heard for a remarkably long distance.

Whooping-cough cannot be cured any more than can typhoid fever. Neither can we prevent children from taking it, except by isolating the cases which are affected. It is claimed, however, that small doses of quinine seem to exert a slight prophylactic action, protecting children who have been exposed to a certain extent. Quinine, it is known, has a distinct anti-bacterial or germicidal effect, and in the case of any adult who has never had the disease and who is exposed to this infection, a weak quinine spray to the fauces may be beneficial in averting an attack if the patient is willing to stand the bitter taste of the drug. This treatment has also been recommended highly for children, but it is practically impossible to use a spray upon a child. We must, therefore, either force the child's mouth open and paint the fauces, or we must rely upon the drug given by the mouth, together with some anodyne. I do not mean to say that whooping-cough is a disease affecting the fauces, but that treating the fauces in that way seems to alleviate the trouble greatly.

Pneumonia and exhaustion and capillary bronchitis are the two conditions which most frequently kill these children, especially if they are young children. Whooping-cough rarely, if ever, produces a fatal result directly from suffocation. If we do find a case in which the cough is exceedingly severe, we may use inhalations of the nitrite of amyl on the hand or upon a handkerchief. Two to three drops of the drug is sufficient. Another treatment highly recommended is the inhalation of chloroform. This is disagreeable to children, and if employed the proportion should be five parts of the chloroform to ninety-five of air. Ringer recommends pouring half a drachm of the chloroform upon the hand of the nurse and holding it under the child's nostrils. The child will soon learn to take a couple of whiffs, enough to postpone the paroxysm. There is no danger in this unless the child has a weak and dilated heart. The only disadvantage connected with its use is the placing of a dangerous drug in the hands of the people. Children often come to learn of the relief chloroform affords and run to their parents for it when the paroxysm is coming on.

In certain cases in the lower walks of life we cannot use these drugs because of the cost and the danger. We then resort to antipyrin, which I regard as the best remedy discovered in the treatment of whooping-cough as yet. Occasionally we must push it until we get the physiological effect, two grains every three hours to a child of 10 or 12 until we get the effect, and then every four or five hours. We must watch the effect of the drug carefully, stopping on the appearance of any bluing of the face or finger-nails. If I were giving antipyrin to a child of this age, and were to sit down near it, I should not notice the cyanosis probably, while were I to sit at a distance from the patient it would be quite distinct. This is a curious effect of the drug which I have frequently noticed. Usually the cyanosis first appears under the thumb-nail, as it does when using antifebrin, but the fingers are often blue from cold, and it is best to notice the face. For a child of this age (4 years) I should give one grain in water every two or three hours.

Often children with whooping-cough suffer with fever at night, which may be severe. In such cases we use antipyrin, stopping the use of the drug at once if profuse sweating is produced, as this further exhausts the patient. We know that any drug which produces sweating acts as a depressant upon the system. Antifebrin, phenacetin and the other coal-tar products probably also exert some favorable effect upon whooping-cough, antifebrin positively so. But they are all more dangerous than antipyrin, and must be given in smaller doses. Before the introduction of antipyrin, belladonna, small doses of opium, and other antispasmodics were used in this disease. Potassium bromide is of great service, especially at night, to produce sound sleep. It is well to use the bromide at night together with antipyrin during the day. Belladonna does good by decreasing reflex action. It was formerly supposed, and probably it is so, that the whoop was produced by some reflex irritation of the bronchial mucous membrane. It is due to a closure of the glottis followed by a very sudden inspiratory effort. It is, in fact, a long drawn-out hiccough, without a total closure of the glottis as in hiccough, but only a partial closure through which the air rushes with the production of the characteristic sound.

In some cases of whooping-cough ecchymoses occur, especially in the conjunctivæ, and at times hemorrhages occur, from the throat, nose, or hemorrhage occurs from the ear. On the other hand, some cases are attended by no bleeding at all. From a study of the physiological effect of aconite and veratrum viride I have thought that in these cases of hemorrhage we may by using these drugs produce a fall of the arterial pressure and thus prevent the occurrence of the bleeding. The asphyxia produced by the violent coughing gives rise to a rise of arterial pressure, and a rupture of the small blood-vessels follows with the production of ecchymoses. Now, by giving graduated doses of these drugs we may be able to prevent this terrible strain upon the heart and arterial system and thus prevent this complication.

The symptoms of an oncoming pneumonia are sometimes those of the catarrhal form, sometimes of the croupous. This comes on because the chest and lungs are weakened and congestions readily occur. If the pneumonia occurs in a week or two weeks after the commencement of the disease, it may be a croupous inflammation, but coming on late in the course of the disease it is generally catarrhal in nature, often bilateral, and affecting usually the lower lobes posteriorly.

The parents generally inquire as to how long the child will be sick with pertussis and you can safely say six weeks at least, or perhaps it may be eight weeks. German writers put the limit at sixty-two days, and during this period the child should be isolated as far as possible from other children. Occasionally in the course of the disease the child will swallow a large amount of mucus. A gastro-intestinal catarrh results and a lienteric diarrhæa follows, the child dying rapidly of exhaustion. With every cough the child will have a passage, and it will cough every five or ten minutes. Such cases are very discouraging.

Green Stools.

The next case I have to show you is one frequently met with in the treatment of children's diseases, and very readily cured if seen in the first stage, but if badly treated it will run on and may develop into cholera infantum. This baby came in with this history. It has always been breast-fed, and has always been well. A few days ago it was given some crackers or cake, and a few days later its stools changed from the normal infantile passages to small and large watery discharges containing curds of milk, and staining the diapers green. The passages were either passed green, or turned green within five minutes, a condition indicative of fermentation. This condition always arises from a torpidity of the liver. As a rule we get a history of obstinate constipation occurring for a few days before the attack. Practically, therefore, it is a case of biliousness. The child is constantly taking food; this is not digested, and passes out as curds, thus giving rise to a lienteric diarrhœa. Generally one grain of calomel divided into twelve powders, and one given every fifteen minutes until one-half a grain is taken will cure the condition. After giving this, warn the parents not to be alarmed if the child has an increase of its diarrhœa, with passages even worse looking than they were before. One or two hours after the calomel has operated give a very small quantity of bismuth, two or three grains every hour, till the patient has taken four or five doses. The calomel sweeps out the fermenting mass and stirs up the liver; the bismuth is slightly astringent and also antacid. If these cases are treated in the early stage in this way in ninety-nine out of a hundred we can get a cure in twenty-four hours. If not so treated they are apt to develop into severe cases of serous diarrhœa.

If any pain exists, as did in this child's case, we may have to use small doses of sulphate of magnesia, or a teaspoonful of sweet oil, which acts well on the bowels. A spice plaster is also of service in these cases. This consists in a heaping tablespoonful of powdered cinnamon, one of powdered allspice and one of powdered nutmeg; to these is added one teaspoonful of black pepper. These dry powders are stirred together upon a plate; a handkerchief is then spread upon a table, and upon this the spice is laid. Then another handkerchief is laid upon this, and the two are basted together without removing them from the table. Stitches are then taken diagonally across the two handkerchiefs, that is, they are quilted, which prevents the spice from falling to one place. Then while still upon the plate warm vinegar or brandy is trickled upon the upper cloth. The brandy may go through and wet the under handkerchief, but this is not advisable. This is then laid over the child's belly from the pubes to the ribs. The child may writhe a little at first,

but generally it will like the plaster, which is comfortable and warm. This can be left on from twenty-four to thirty-six hours. When removed it forms generally a perfect mold of the stomach, and is quite dry. The lumps may be broken up, again moistened and again applied. The pepper is a counter-irritant, the nutmeg and cinnamon are sedatives and the aromatic oils are absorbed to some degree and prevent griping. Should the child pass beyond our control while using calomel we should then administer astringents with care.

COMMUNICATIONS.

MALARIAL FEVER, WITH INTENSE LIVER INVOLVEMENT.

BY ENOS T. BLACKWELL, M. D.,
CEDARVILLE, N. J.

It is much to be wished that the terms applied to diseases or aberrations from health might more nearly express the pathological changes connected therewith. In many cases this is impossible, from the limitation of our knowledge respecting the origin and nature of the infliction. Many efforts have been made towards amendment in this particular, with only partial success. The malady to which I devote this paper has been named bilious fever, remittent fever, malarial fever, pernicious fever, etc. None of these terms appropriately expresses our notion of the fever, judged by its best known phases, much less if judged by its exceptional forms. We must be content, therefore, for the present, to accept, to some extent, the nomenclature in vogue. I do not purpose to speak of the origin of our autumnal fevers; for that is not yet positively established, and I have nothing to offer beyond the accepted theories. My design is to describe, as far as I am able, a very interesting and dangerous case that came under my consideration at a very critical period in its career.

Mrs. H., about fifty years old, is the wife of a dairy farmer, residing in a valley which formerly was much infected with malaria. She has an hepatic trouble of many years standing, and had complained for three months, especially, of pain in the right hypochondrium, which became so severe at times, and especially on lying down, that she was compelled to grasp the side with the hand, in order to limit the movement of the ribs, and so to diminish the suffering. She was unable to lie upon the side, and her bowels were greatly constipated. She is a woman of great vigor and activity in her household affairs, in prosecution of which, at the end of a most wearisome day's labor which involved severe lifting, she suddenly fell sick, and so remained for three or four weeks before I was called to assist in her treatment. I submit her own report of the salient points in her case, which is fuller than any I received; and has the marks of accuracy. It bears date November 27, 1889, and is the first fruits of her convalescence.

"I was taken with a chill, which lasted about two hours and was succeeded by a high fever; the temperature attaining 105° F. For three succeeding days I had chill and fever in alternate paroxysms, of about the same length, to the number of seven. During the chill I was extremely sick at the stomach. When the fever came on, I ached all over and could not rest. This weariness began as soon as I was taken sick; but, as I grew worse it increased. During the next four days I had no chill, but I constantly grew weaker. I had no appetite and slept but little. The pain and tenderness were great from the beginning; and increased as the days wore on. On the tenth day I had a chill and grew worse very fast. The headache and pain in both sides increased, and the sickness also. I was very thirsty, and swallowed a great deal of cracked ice, but no food. I was stimulated with alcohol, taking a teaspoonful of brandy once an hour, if I was able. Sometimes the intervals were longer. I never vomited very much at a time. The vomited matter was frothy and greenish; occasionally, there was in it a little blood. It was very bitter. The sick feeling that I had was terrible. I felt as if my stomach was throbbing, or turning over. I could lie only on my back; and no change could be made in my position, except as I was lifted. The weariness was very great—more than I can express. The burning in the stomach commenced after I had taken so much brandy. Then wine was tried. Whatever entered the stomach irritated it. Diarrhœa commenced about the sixteenth day, the stools being dark and resembling tar. It lasted a week, and then I became very costive."

On September 27, 1889, I first saw this

patient. She was profoundly weak, and could have her head raised only momentarily to facilitate swallowing. She lay altogether upon her back, and her voice was faint and weak. Her pulse was exceedingly small and feeble, and beating 90 times per minute. Her breath was mawkish and fetid. Her tongue was very foul, except just at the tip. She complained of nausea and extreme burning in the epigastrium. The alvine discharges were bronze-colored and very offensive. There was extreme tenderness beneath the free edge of the ribs. The liver boundaries could be traced very accurately in the right and left hypochondrium, and across the epigastrium, by the tenderness alone. The lower boundary of the painful area stopped abruptly with the verge of the liver, and did not at all involve the stomach. The disturbance of that viscus was purely functional and sympathetic. Through the attendants I learned that, when the disease broke out afresh in the second week, it was with extreme violence, the pain being exceedingly acute, and the vomiting severe and long continued. Collapse occurred during one of the paroxysms; and she lay as one dead. Partial recovery followed, and life continued with great weakness and extreme nausea and distress. The attending physician at first termed the disease "Malaria"—a cause for an effect. As the symptoms increased in gravity, it was named "Pernicious Fever." The consultant, who was called a few days before me, called it "Gastric Fever," a term which the attending physician interpreted as inflammation of the stomach, or gastritis.

The treatment in the early days of the disorder was sulphate of quinine in large and progressively enlarging doses; the extreme being eight grains every two hours; or ninety-six grains in a day. Mustard had been perseveringly applied across the suffering part, followed by a blister a few inches square to the right hypochondrium. To appease the intense stomach disturbance, chloroform and bismuth subnitrate had been administered. As an alterative—and, I suppose as generally useful—calomel was given; and as a diffusible stimulant, brandy, some drug being imposed on the unhappy stomach, every fifteen minutes. The stomach was the great object of attack, as this was believed to be the rock of offense. By the advice of the first consultant, the mercurial, which had been used perseveringly, and in great quantity, was omitted, and nitro-muriatic acid was substituted. The other medicaments were continued. The change was for the worse, rather than the better; the ejections becoming intensely sour, the epigastric heat aggravated and the nausea intensified.

It was now evident that the treatment was unsuited to the pathological condition, and must be changed to insure success. My advice was in line with my diagnosis. Because of the presence and precedence of the hepatitis, and the absence of tenderness over the stomach, I judged that the liver was mostly in fault; that the disease was emphatically a bilious fever, so called, and that the treatment should be directed especially towards this, the point first affected.

In deference to my age and experience, as well as to my relation to the patient, the attending physician, under protest, permitted the following treatment, all else being omitted.

℞ Potassii iodidi . . . . . ʒj
Potassii bicarb. . . . . ʒss
Aquæ . . . . . fʒiss

M. Sig. A teaspoonful, in water as hot as can be drank, every four hours.

℞ Acetanelid
Cinchonidiæ sulph. . . . . āā ʒss
Pulv. opii . . . . . gr. ij

Mix, and make fifteen pills, one to be taken every four hours, alternately with the preceding.

My *confrère* apprehended grave results from the action of the liquid mixture, and waived all responsibility for the consequences. This was at 9 o'clock A. M. There was little change in the symptoms during the forenoon; the burning in the stomach, the sourness and bitterness in the mouth, and the pain continuing much as before.

During the afternoon and evening there occurred three or four greenish-black stools. At bedtime, to relieve the pain and to procure sleep, one-quarter grain of acetate of morphia was given; the other prescriptions to be persevered with.

September 28, at 9 A. M., the patient's stomach was more comfortable; she had had two movements of the bowels during the night, of the same character as before, but had rested well. The pulse ranged from 90 to 100. The saliva was disagreeable and bitter; but she was able to take some prepared gelatine and beef-tea. Dr.—— saw

her alone. He was agreeably surprised at the success of the treatment, and ordered its continuance. On September 29, the patient rested well, without anodyne. She had some relish for food, taking for the first time some cerealine. Her pulse was 84, and was quite full and of good force. September 30, she had rested well. Her pulse was 80, and of good strength. There had been two more movements—not so dark, but apparently full of globules of bile. October 1, her pulse continued satisfactory; and her voice had been gaining strength for two or three days. She could yet have her head only slightly raised while taking medicine or food, which were continued without change. The bowels were moving two or three times daily, with considerable pain.

At this time I ceased to see the patient; but she gradually improved, and was able near the end of November to write me an account of her experiences. She did not become fully convalescent until late in winter, or the beginning of spring.

The mistake in attributing the intense epigastric distress in this case to inflammation of the stomach, and the attempt to relieve it by medicines acting directly upon its mucous membrane, vitiated much of the early treatment, many of the drugs increasing the irritation and retarding recovery. This mischase clearly arose from the failure to recognize and appreciate the tissue or organ positively at fault. This could be easily accomplished with care, as the differential boundaries of the liver and stomach could be accurately mapped out by using the proper physical tests. The impropriety of such "whips" as brandy and chloroform, and their injurious influence, was amply shown by the subsidence of the stomach irritation, and the regulation and strengthening of the pulse which followed their withdrawal. The change for the better succeeded immediately the change of treatment, and is attributable to the subsidence of the hyperemia of the portal vessels, through the influence of the iodide of potassium, the potations of hot water, and the withdrawal of irritants and stimulants.

Castor oil has been found adulterated with resin. If shaken with nitric acid the adulterated oil becomes deep brown, and the acid layer assumes a yellow color. With pure castor oil the acid remains unchanged, while the oil assumes a light brown color.

WAS IT RELAPSING FEVER?[1]

BY A. D. BARR, M. D.,
CALAMINE, ARKANSAS.

The following is the description of a continued form of fever that came under my observation in the latter part of 1888. At first I thought it to be malaria, and treated it accordingly; but I soon found that antiperiodics had no influence over the disease. I then abandoned all treatment, except to modify the symptoms when they were dangerous. When the fever exceeded 103° F., an antipyretic was given; and this was always acetanilid or quinine. When the nausea and vomiting were prominent some form of opium was used. During the first intervals nux vomica, arsenic and quinine were administered to prevent a return of the paroxysms, but without success. The natural course of the disease was carefully studied, uninfluenced by treatment, and the symptoms noted at the time furnish the data of this article. It was a self-limited, continued form of fever, the distinctive feature of which was three or more relapses. The recurrence of fever, as before stated, was the distinctive feature. Abruptness of invasion was characteristic of the disease. There was no prodromal or incubative stage. The seizures were never ushered in by a distinct chill; though chilly sensations were complained of, followed by a rise of temperature, usually sufficient to cause the patient to take to bed at once, though it sometimes required one, two, or even three days for the temperature to become sufficiently elevated to produce such a result. Perspiration seldom occurred until the fever began to decline. The fever attained quickly to considerable intensity, often reaching 103° or 104° F., within twenty-four hours. In one case the fever reached 104½° F. on the evening of the first day. This was, however, a relapse, instead of the primary attack. During the paroxysms the temperature denoted a persistent intensity of fever, ranging from 100° to 105° F. There were no oscillations; the temperature either gradually or rapidly reached its maximum, and then it maintained about the same elevation for from one to fours days and sometimes longer, and usually subsided gradually. The duration of the

[1] Read at the sixteenth Annual Meeting of the Mississippi Valley Medical Association, October, 1890.

primary attack varied from six to twelve days.

During the intermission, the absence of fever and all other symptoms was complete. The period of intermission varied from two to twelve days, the average being about seven. The relapse, like the primary attack, was sudden, and was also generally ushered in by chilly sensations, though the first symptom was sometimes an elevation of temperature. The fever in the relapses suddenly became more or less elevated, usually more elevated than in the primary stage. The relapses also generally subsided gradually, and with moderate perspiration. Their duration was from four to ten days, and the greatest number was five.

Of symptoms referable to the digestive system, nausea and vomiting occurred often enough to be somewhat characteristic. They were generally prominent features, but they were not always present. They were frequently so severe that the patient was in danger of sinking from exhaustion or collapse. The vomited matter generally contained bile, and not infrequently blood. The tongue was generally coated with a white fur, but sometimes became dry and cracked. Diarrhœa was very infrequent. Constipation was the rule. Tenderness over the epigastric and iliac regions occurred to a very moderate degree. The appetite was often impaired, but not to the extent that is usual in most diseases where the temperature is elevated to as high a degree as it was in this case. Sometimes there was a noticeable craving for food, so much so that it was highly distinctive. During the paroxysms, pain in the muscles of the small of the back and the calves of the legs were complained of. They were never entirely wanting, though they varied in intensity.

The perceptions were not blunted in this as in various other diseases. Delirium was present sometimes; but it was of that character which is likely to occur when there is a high febrile movement, without regard to the existing malady. The face was usually flushed. The amount of urine was usually decreased. The decrease in one instance amounted to complete suppression for twenty-four hours; and the kidneys acted badly for several days thereafter; which in turn was followed by an excessive diuresis. A copious flow was apt to occur about the cessation of each seizure.

Regarding the cause of the disease, I am unable to give any satisfactory statement. In one case it seemed probable that it was contracted by contagion, as the child was in frequent contact with a young woman suffering with the same disease. The disease seemed at times to be developed spontaneously.

In regard to treatment, all that I could do was to modify the symptoms. The disease was essentially a self-limited one, and was uninfluenced by all treatment instituted by me. Quinine, given in five or ten grain doses, from two to six hours apart, seemed to aggravate the condition by increasing the nausea and vomiting. Calomel also seemed to retard convalescence. The nausea and vomiting were best controlled by morphine and Listerine. In the first stage the pains were often so severe as to call for an anodyne; but as a rule when the temperature was reduced below 100° F., they subsided until the fever again became intense enough to call for a repetition of the antipyretic. Good, plain, wholesome food was allowed.

Society Reports.

SUPRA-PUBIC CYSTOTOMY.

DISCUSSION AT THE SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION, NOVEMBER 12, 1890.

In discussing the paper of Dr. Cobb (see p. 7).

Dr. G. Frank Lydston, of Chicago, said we must necessarily consider the question which, as I infer from the title of his paper, Dr. McGuire would have discussed if he were here, the best route to the male bladder in cases of calculus, and more particularly of prostatic disease.

The revival of the old supra-pubic operation, which had so long fallen into disuse, has, under antiseptic methods, resulted, in my opinion, in a little too much enthusiasm regarding its merits. I think we must be guided by the same wise conservatism that has been suggested here this morning relative to the question of removal of the diseased appendages in the female. I believe that a proper selection of cases is necessary. I do not believe that every case of prostatic disease, of calculus or of enlarged prostate, justifies the performance of the supra-pubic operation to the exclusion of everything else.

There seems to be a tendency in the direction of routinism in this respect. When a calculus is present in connection with an enlarged prostate, and the prostate is very large, particularly if it be suspected that there is hypertrophy, especially some form of hypertrophy in which a distinct tumor is present, or in cases in which the bladder is profoundly involved, it is undoubtedly best to perform the supra-pubic operation. In this way we avoid certain dangers which in severe inflammatory conditions of the bladder are incurred by the performance of the perineal section. One of these is the extreme danger when the bladder is in a condition of chronic inflammation and the urine is strongly septic, and of septic absorption from the perineal wound. There is no question but that the perineal wound is dangerous in this respect, and far more so than a wound inflicted by the supra-pubic operation. The facilities for absorption are greater, and the tract over which the urine is allowed to flow is more important. It is desirable to avoid this absorption, and in cases of extreme bladder disease in which the urine is highly septic the supra-pubic operation is the best.

Another consideration—and it is one of the principal dangers we have to contend with in operations upon the male urinary apparatus—is shock. It is not only injurious *per se*, but indirectly, by reflexly suppressing the function of the kidneys. The shock in supra-pubic section is much less than in the perineal operation. Where this consideration is of importance, it is undoubtedly better to perform the supra-pubic section. If there is a large stone, or if there is any portion of the prostate that is susceptible to surgical measures, the opening of the bladder from above of course facilitates matters. It is a difficult thing to accomplish removal of a portion of the prostate through a perineal wound. Some surgeons have reported extraordinary cases which have been operated on by electrolysis and by the galvano-cautery. I would rather see the operations than read of them. I would have to see them performed in order to be convinced of their utility. Briefly, then, in cases in which the urine is highly septic, in the cases in which the kidneys are disturbed, in cases in which it is desirable to avoid shock, and in cases where operation on the prostate is contemplated—*i. e.*, where the removal of any portion of the prostate is deemed advisable, the supra-pubic operation is undoubtedly the best. When a calculus is small, provided that we decide upon a cutting operation rather than upon litholopaxy with the bladder in good condition, and when the prostate is not extremely large, if any operation be done in the way of exploration of the bladder, the perineal operation should be preferred. Danger is avoided by the procedure of Reginald Harrison, which consists of the introduction of a rubber tube into the bladder, thus avoiding contact of the septic urine with the tissues; this is a modification of Cock's operation.

When symptoms of serious systemic poisoning exist, the supra-pubic operation should be selected. I mean by this, not symptoms of uræmia so-called, but that peculiar toxæmic state incidental to the absorption of ptomaines, which characterizes many chronic diseases of the urinary organs. This systematic poisoning is noticed in a minor degree even in some cases of relatively slight strictures. I do not think that the supra-pubic operation is any better from the standpoint of drainage than the perineal operation, but where drainage is to be prolonged it is much more convenient in this situation. Again, absorption, as I have already remarked, during the removal of the septic material by washing of the bladder and during the spontaneous draining away of the urine, is not nearly so apt to occur as when the operation is done in the perineum.

In perineal operations, after the danger of shock has passed away, there is danger of septic infection in direct proportion to the frequency with which the urine is allowed to come in contact with the wound. The same is true of internal cutting operations in stricture. It will be found in many cases that the patient will be pretty comfortable until the first time he urinates, when immediately a chill followed by fever is set up, and very often goes on to a fatal issue, with all of the symptoms of profound septic poisoning. The tract of the wound in the supra-pubic operation is not so long, relatively speaking; it does not traverse such important structures, nor are these parts so well endowed with sensitive nerves and absorbents as is the case with perineal wounds.

Dr. John D. S. Davis, of Birmingham, Ala., said: I cannot accept the statement that the perineal incision is the best for draining the bladder when we have no enlarged prostate. I have done Reginald Harrison's operation a number of times. I have observed

the results of the perineal incision many times, and in no case have I got as good results as by supra-pubic operation for draining the bladder *per se*, from the simple fact that the tendency of the perineal incision is to close before the pathological conditions in the bladder subside, while with the high operation it does not close so readily. I do not think the high operation is the ideal one for the relief of stone. I think the bilateral incision (perineal) is the best, that is, in cases where you have no enlarged prostate. It is best for the removal of the stone where you want no after drainage. Where you want after drainage, my experience as well as that of Dr. McGuire and other surgeons, proves conclusively, and beyond any possible doubt, that the high operation is the best.

I have a criticism to offer regarding the technique of the operation. I do not agree with Dr. McGuire in regard to making his coffee spout fistula. He discarded it over a year ago, and now follows my technique. I have three methods for making the fistula:

1. When the distension is great and no intra-vesical operation is necessary, the opening is made with a trocar, withdrawing the stylet and replacing it with a rubber catheter, after the introduction of which the canula is withdrawn, leaving the catheter in the bladder. It is necessary sometimes to enlarge the external or cutaneous opening to prevent a closure of the catheter by compression, and to render the external opening sufficiently large.

2. The bladder may be opened, when distended, by a direct incision with the knife, in the median line, with cutting edge towards the symphysis pubis at an angle of forty-five degrees. The knife is withdrawn and a catheter is introduced through the wound into the bladder.

3. A perpendicular incision, one or two inches, is made in the median line above the symphysis pubis. If the pyramidalis muscles are in the way the fibre should be cut. The transversalis fascia is divided on a grooved director from symphysis to upper margin of superficial wound. Instead of following Guyon's manœuvre I catch the bladder with a tenaculum on a line with the symphysis, through the pre-vesical fat, and cut with a bladder knife into the bladder with one smooth, clean incision, to prevent undue disturbance of the cellulo-adipose tissue between the bladder and pubes, and avoid infiltration. I have never seen a case where it was necessary to push up the pre-vesical fat, and with it the peritoneal cul-de-sac. If the bladder is caught on a line with the symphysis and cut downward, no fears need be had for the peritoneum. Cutting this pre-vesical fat prevents its after dropping down over the opening into the bladder, and acting as a valve to prevent easy access to bladder, escape of urine, and causing infiltration.

I agree with Dr. Lydston that the shock is much greater in the perineal operation, but this operation is the ideal one in my judgment for the removal of stone, where no after drainage is required; but where we desire after drainage the high operation is the better.

The fistula is made competent by a pseudo-sphincter formed by the fibres of the detrusor urinæ muscle. In all my cases there is the power to retain and expel the urine at will regardless of the position of the body.

Dr. Joseph Price, of Philadelphia, said: Some of the gentlemen differ in method from the distinguished gentleman that devised this operation, and surely they deserve credit for perfecting it. Dr. McGuire, I believe, has rejected all perineal operations for the removal of stone, and he looks upon this as the most perfect of all methods of dealing with vesical troubles, whether disease or calculus. He has now so completely perfected the operation that he tells me he has a number of men traveling about passing their urine at intervals of every four or six hours at ease, having perfect control of both the bladder and its contents, passing the urine in a stream and suffering no inconvenience from the new channel for voiding their urine. He expresses his regrets that he has done so many perineal sections for stone.

What Dr. Davis has said in regard to drainage I concur in. You can drain anything above the pubes and drain it successfully. It is curious to note the results of the two schools, one advocating vaginal drainage, and the other supra-pubic, the first following the methods of Martin and others of puncturing the vaginal wall and draining from the vagina, and the second that of drainage from above. The results are that Martin lost by vaginal drainage fourteen in 77 cases of pelvic operations, a mortality that should stay our hands in such work.

Dr. W. E. B. Davis, of Birmingham, Alabama, said: I would not detract any of the honor of this operation from Dr. McGuire.

Dr. McGuire is a great surgeon and has done good work in this direction. I believe with him that this is the ideal operation for stone or for cystitis. The reports of the histories of Dr. McGuire's cases are not satisfactory. We can get but little idea of the after treatment. My brother (Dr. John D. S. Davis) has operated on more cases than any other man in the South except Dr. McGuire, and we have had an opportunity of following these cases, and have found that it is a good deal of trouble to keep the fistula open. Every two or three weeks patients will come to you complaining of some trouble in the fistula. I have seen abscesses form in some cases. Dr. McGuire, you remember, when he first devised the operation, suggested sewing up the lower part of the wound, making a coffee-spout fistula, allowing the urine to come out at the top of the wound. My brother followed Dr. McGuire in the case of a man with cystitis. He tried to keep the fistula open; but an abscess formed at the lower angle of the wound. I insisted upon removing the tube from where it was and placing it in the bladder through the opening made by the abscess, but he said he was going to follow Dr. McGuire's technique. However, the urine did come through the abscess opening and proved the best operation to be *direct supra-pubic cystotomy*. My brother was the first, I think, to read a paper on this subject.

Dr. McGuire deserves a great deal of credit for the operation, but for the technique of the operation, the credit should be given where it belongs. We have done the direct incision a number of times. It is the ideal operation. We do not want to make a long canal. It is not a lengthy canal that controls the urine. There is no question but what patients will pass their urine voluntarily through the direct fistula just as they do through the natural passage.

The trouble is that these cases, where we resort to supra-pubic cystotomy for drainage in prostatic troubles, come to us too late. This is well illustrated in the case of an ex-vice-president of this Association, Dr. R. D. Webb, a man who has written most valuable papers on this subject, advising early operation. Dr. Webb, however, neglected his own case until he was almost dead. He had been unable to pass urine except through a catheter for a great many years, and for the past six months he had been compelled to draw it off frequently. He was having severe paroxysms of pain constantly. While he has been greatly relieved by the operation, which I performed more than two months ago, I doubt whether he will be able to go about his work again. He waited too long. The prostate was enormously enlarged, and when we came to do the operation we had great difficulty in finding the bladder, which would hold only two or three ounces of urine. We would insist on early operation in prostatic cases.

Dr. Geo. A. Baxter, of Chattanooga, Tenn., stated that one of his recent cases was such an apt illustration of some of the points made in reference to supra-pubic drainage and the danger from septic infection by drainage though the perineum that he felt compelled to make a report of it.

The subject, a former doctor of medicine, between 70 and 80 years of age, suffered severely from enlarged prostate, and was in the habit of relieving himself of occasional attacks of retention by using the catheter himself. During a visit to some mountain springs, thirty miles distant from Chattanooga, he suffered one of these attacks of retention, but failed to enter the bladder. A neighboring physician was called in and failed also, and he was sent post haste to me. He reached town in the night, and called temporarily a very competent physician, who found him over a vessel with a long silver catheter pushed up to the hilt, but not in the bladder, and examination disclosed the fact that this had been done frequently, so that it was impossible to tell where the real canal was, so ruptured and torn was the whole urethra. I saw him early the next morning, and with the doctor last in attendance determined upon aspiration rather than further trial to enter the bladder by the natural passages, or by perineal operation, after first confirming the condition as reported to me, for the following reasons:

1. The bladder was immediately distended and had been so for forty-eight hours, hard as a rock and seemingly likely to burst at any moment, rendering immediate relief imperative.

2. I thought and still hold that a route through the perineum or the urethra simply would have necessarily produced infiltration, sepsis and death.

The man was unconscious by this time with stertorous breathing, weak, fast pulse. I aspirated, but had to turn the needle a little to the left side before the bladder was entered. I followed the immediate supra-pubic cystotomy for the purpose of complete drain-

age in order to protect the parts lacerated by himself, put in a large double tube and washed the bladder out with boric acid. That I was right was evidenced by his condition, and he died either as the result of uremia, from which he was suffering when I operated, and from which he was only partially relieved, or from exhaustion of his long continued suffering and generally prostrated condition, I do not know which, but it matters little, as the case is here related for the illustration of points in other directions made by the gentlemen discussing this subject.

Dr. F. W. McRae, of Atlanta, Ga., said: With regard to the termination of some of these cases, I desire to exemplify the statement which Dr. W. E. B. Davis has made. The operation is frequently delayed too long to be of benefit to the patient.

I operated on a man, aged 72 years, last summer, who had been suffering for five or six years from supposed prostatic disease. He had been under my care but a short time, when an attack of cystitis occurred. I examined him for stone and was unable to find it. I finally decided to do the suprapubic operation with drainage, and after cutting down and opening the bladder I found a stone embedded underneath the prostate, which I removed. This patient—I will say by way of parenthesis—had in the last five years two strokes of hemiplegia. He had been paralyzed on one side twice and was not in the best physical condition for the operation. I did the operation as suggested by Dr. Davis. The case progressed nicely until the fifth day, when the patient suddenly died. I didn't have a chance to make an autopsy; but the presumption was that he died from some cerebral trouble. The wound was opened, which I found had perfectly healed, except opening left for drainage-tube, and there was no apparent suppression of urine.

Dr. W. H. H. Cobb, of Goldsboro, N. C., said: Some of the interesting points in my paper have not been touched upon in the discussion. First, the patient's age. Being only 49 years old, he was rather young for enlarged prostate. Then the etiology—what was the cause of prostatic enlargement in this patient? Could it be attributed in part to his rheumatic diathesis? And is it not unusual to find so many symptoms simulating vesical calculus? the patient having, in addition to his terrible cystitis, the sudden arrest of urine, which was relieved by change of posture, with great pain in the glans penis. The symptoms were so urgent that the operation was performed simply to save the patient's life. Had the case been allowed to progress much longer, the inflammation would have traveled up the ureters to the kidneys, and the operation would have proved useless.

Periscope.

Hepatic Colic.

In a recent number of *La Médecine Moderne*, Professor Germain Sée discusses the always interesting and important subject of the treatment of hepatic colic. The obvious primary indication is to promote the expulsion of the gall-stone, and this, Professor Sée urges, should be accomplished by remedies which increase the flow of bile. The sufferings of the patient are, however, usually so intense that we are compelled to consider first the application of measures directed to the relief of pain. Of these by far the most speedy and effectual is the hypodermic injection of morphine. This usually acts very well, but Professor Sée warns us that in some cases the patients, after a fit of vomiting, fall into a state of alarming collapse, even when only one centigramme of morphine has been injected. We must also bear in mind that morphine is one of the substances which diminish the biliary secretion. Of antipyrin Professor Sée says that "it will only render mediocre services in this matter, and that we should not lose time by prescribing it." Chloral and chloroform have a less certain action than morphine, but possess the advantage of not hindering the secretion of bile. Professor Sée advises that chloral, if used at all, should be given by enema, as it will not be well tolerated by the stomach. He is disposed to believe that both chloral and chloroform may act favorably by relieving spasm and promoting the relaxation of the walls of the bile-duct.

The second and most scientific indication is to increase the biliary secretion. The mere presence of the gall-stone and the irritation which it excites, have a tendency to augment the flow of bile, but help may be obtained from the use of various medicinal remedies. Of cholagogues Professor Sée enumerates bile itself, turpentine and its derivatives, terpine, terpinol, benzoic acid,

salicylate of soda, and olive oil. He points out that bile is inadmissible, as its employment tends to make the biliary secretion thicker rather than to render it more fluid, as is desirable. Turpentine and its derivatives are comparatively inefficient cholagogues, but are nevertheless of some value. The "Durande remedy" owed its success to the presence of turpentine. Of two only of the remedies enumerated does Professor Sée hold a high opinion—viz., salicylate of soda and olive oil. The cholagogue action of the former of those, although pointed out by Rutherford, is hardly sufficiently recognized in this country. It seems to increase the entire biliary secretion, but more particularly its fluid elements. According to Professor Sée, it not only acts as a cholagogue, but has also an analgesic effect, which is obviously desirable in the conditions under consideration. It is advised that salicylate of soda be given with large quantities of fluid, as this seems to assist its action.

The cholagogue action of olive oil has been a subject of dispute, and was denied by Bidder and Schmidt. The later experiments of Rosenberg, however, seem to show that if the animal experimented upon be kept upon a normal diet, and olive oil be administered, "a considerable augmentation of the biliary secretion, especially of its fluid part, begins in from thirty to forty-five minutes, the maximum increase is obtained from the third to the fifth hour, and there is also a considerable increase of fatty acids which are capable of dissolving cholestearine." Professor Sée believes that clinical experience proves that the administration of olive oil both promotes the removal of the gall-stone and relieves the attendant pain and jaundice. Its *modus operandi* has been the subject of some fanciful theories. Thus it was at one time supposed that the oil actually ascended the duct and acted locally upon the impacted gall-stone. For this idea there was never any adequate foundation, and it must suffice to say that the administration of olive oil tends to increase the flow of bile and to make it more liquid. The chief objection to this line of treatment is that the oil is often badly tolerated, and that even if it be well borne at first, intolerance is quickly excited.

Professor Sée finally discusses the remedies that are contra-indicated in an attack of biliary colic. Chief among these are those medicaments which tend to excite strong peristaltic movements of the intestine, as these are apt to be propagated to the bile passages. Hence strong purgatives are injurious. Purgation should only be employed after the crisis is over, and even then with caution, as it may excite a fresh attack. Nevertheless, it cannot be wholly dispensed with, as it is desirable to clear out the bile that has found its way into the intestine. We should also avoid those substances which diminish the biliary secretion, of which Professor Sée enumerates the salts of potash, calomel, iron, copper, morphine, atropine and strychnine.

These recommendations—coming from so esteemed a source, and founded upon such ample physiological experiment and clinical trial—will be received with the respect which they deserve. Probably the point which runs most counter to ordinary practice is the advice given regarding the use of purgatives. At the crisis of the malady, when the duct is contracting violently and the patient is in extreme agony, no one would dream of giving a purge; but a little later on, when the pain has been subdued, while the impaction remains and jaundice is deepening, moderate purgation with such an agent as Glauber's salt has often proved the most efficient of all methods of treatment. Turpentine does not seem to have justified the hopes that, on theoretical grounds, were raised regarding its value in biliary colic. Salicylate of soda and olive oil are well worth a trial, and Professor Sée's recommendation will ensure their wide employment. Whatever medicinal remedies we select, it seems evident that copious draughts of warm water, to which a little soda has been added, are invariably advantageous, and it is well that so simple a measure should not be overlooked or neglected because of its simplicity.—*Lancet*, December 13, 1890.

Grafting Skin from the Dead Body.

The *Annals of Surgery*, November, 1890, says that in 1888, Drs. Bertens and Werner described a remarkable case of a boy, with intractable extensive ulcers of the legs, in which they had successfully transplanted 24 skin grafts excised from the body of a woman 75 years old about twenty minutes after her death. The perusal of this paper induced Dr. Sophia Ivanova, of St. Petersburg, to try their method in the case of a poorly-nourished woman, æt. 75 years, who had received a burn of the third degree involving the

whole leg and dorsal aspect of the foot. In about a fortnight the injured integuments sloughed away to leave an enormous freely suppurating granulating surface. The grafting, resorted to shortly after the separation of the sloughs, was made at two sittings, with an interval of three and one-half weeks, the material being derived from two new born infants' bodies, one and one-half and two hours after the children's death. During the short period elapsing between the excision and transplantation, the strips and pieces were kept in a 6:1,000 solution of chloride of sodium at 40° C. Every one of them became firmly adherent to the surface in 48 hours, while in two or three days the epidermis began to grow around all the grafts. Speedy and sound healing ensued. Dr. Ivanova believes that this method offers undoubted advantages over Reverdin's plan, in securing more rapid healing of lesions and lessening the injurious effects of prolonged suppuration and lying in bed; it gives better functional results, through preventing cicatricial contraction; the material is easily obtainable in abundance, and that without inflicting suffering or inconvenience to any human being.

The skin must always be taken from bodies of patients who have not had syphilis, septicemia or any other infectious disease. The best material is afforded by bodies of new born infants of healthy mothers, the infantile tissue possessing most energetic vitality.

It is advisable to employ rather long strips, measuring not more than an inch or so in width. Small sized pieces are easily washed away by pus or blood. Only the skin proper, freed from all subcutaneous cellular tissue, should be transplanted. If the granulating surface is clean and not very weak, no scraping is necessary. It is sufficient to previously thoroughly wash the surface, after which the grafts should be carefully adjusted and slightly pressed down with dressing.

The best dressing material is gauze soaked in a boric acid solution, and then wrung out. This tissue absorbs secretions very well, never becomes adherent to grafts, and hence may be easily removed without disturbing the latter.

The transplantation must be practiced as early as possible; thus in cases of deep burns, it should be resorted to immediately after the separation of sloughs. When large-sized strips or pieces are used, even a free suppuration cannot prevent their adhering to the surface.

Liquid Pepsins.

The *Chemist and Druggist*, October 18, 1890, says Mr. D. L. Haigh has been abusing liquid pepsins before the Missouri Pharmaceutical Association. Amongst the things he said, and which will have occurred to many pharmacists, was that among the simple solutions of pepsin which are objectionable are the wine, elixir, aromatic elixir and elixir of pepsin and bismuth. In the last preparation the ammonio-citrate of bismuth is used. To hold this in solution it must be either slightly alkaline or neutral. Pepsin, on the other hand, must be in acid solution or it will decompose and very likely precipitate. The two substances are therefore incompatible, and the preparation is almost worthless. This is a very simple case. How is it with an alkaloid added, as in elixir pepsin, bismuth and strychnia? It is known that alkaloids must either be held in solution by means of a solvent—generally alcohol—or be converted into soluble salts by an acid. This last preparation, then, must be neutral to be stable. How long can this be the case with such a loosely-constructed salt as ammonio-citrate of bismuth, when the ammonia is being constantly carried off? The popularity of pepsin has carried its use to the extreme; although it is an invaluable remedy, like many good things it is abused. The only way to administer pepsin is in the solid form, preferably in powder. The vast number of scale pepsins are for the greater part peptones and do not possess the digestive power of the powdered pepsins. In fact, the highest digestive power pepsins are not soluble to any extent, which is another very potent reason why this article should not be used in liquid form.

There is truth in some of Mr. Haigh's statements, but he has not carried his inquiries far enough. Liquid pepsins can easily be made which possess high digestive power. For years we have pointed out that the minimum amount of alcohol should be used for the preservation of these preparations, as alcohol in certain amount precipitates the ferment. Mr. Haigh appears to overlook the fact that the pepsin ferment is a soluble body. We have no evidence that it is insoluble in alkaline media; the question is: Is it desirable to administer it in such media? We know that in that condition it is inactive, but how long will it remain alkaline in the stomach?

That there is great ignorance regarding

pepsin is evidenced by the fact that some time ago a medical journal, whose opinion is highly valued, stated that it had tested one of the pepsin preparations which Mr. Haigh objects to, and from the amount of *starch* which it converted, it had been led to form a high opinion, etc. The manufacturers actually advertise this testimonial!

Peroxide of Hydrogen.

The *University Medical Magazine*, December, 1890, says editorially that peroxide of hydrogen is a drug which has been gradually and steadily gaining in favor, and which has yielded to each who has faithfully tried it results so constant and so satisfactory that he has learned to depend upon it. As ordinarily found in the shops, peroxide of hydrogen is a 3.2 per cent. solution, yielding fifteen times its bulk of oxygen. This solution is far more potent than is water charged with fifteen times its volume of oxygen, since in the peroxide preparations the gas is given off in its nascent state and is peculiarly powerful in its chemical affinities.

There is abundant evidence as to the value of the peroxide, from both the clinical and the experimental standpoint. The number of those who have reported excellent results from its use is very large, and to this must be added the testimony of the bacteriologists, who find in this drug a potent and almost immediate germicide. It is devoid of septic properties, its worst effect being, when used in a too concentrated form, to cause some local pain and irritation. It is applicable in all cases where pus is present, and where the discharge is foul and profuse its effect is admirable. In suppurating otitis media, in purulent conjunctivitis, the aurists and ophthalmologists have long prized it as one of their most valuable medicaments. In the sloughing inflammations following scarlet fever and diphtheria, the laryngologists place great confidence in its powers. Surgeons, however, in whose work it might prove generally valuable, have been somewhat slow to recognize its virtues. But its use in a great variety of sloughing and suppurating cases has given results better than those obtained from any other germicide—bichloride of mercury not excepted. Where the discharging area is represented by a surface of granulations, the drug can be applied by means of an atomizer. This enables a small quantity to reach every portion of the infected surface. In the case of a suppurating fistula or cavity, the peroxide may be injected by means of a syringe. Immediately following its application to a purulent surface, an active effervescence goes on, and every particle of pus which it reaches is destroyed. Not only this, but the microbes, the active agents of pus formation, are also devitalized, so that a large surface can sometimes be rendered aseptic by one or two thorough applications. Even if this result is not reached, the discharge is greatly lessened, and it is by no means uncommon to see a case, in which the pus had amounted to drachms, so favorably affected that the dressings contain but a few drops of purulent matter.

The strength in which the fifteen volume solution is used will vary with individual cases. It can be employed without harm in full strength. Where this is painful, one, two or four parts of water may be added.

Fatal Uremia in Persons Apparently Healthy.

The *New York Medical Journal*, November 15, 1890, says Dr. A. Westphal has described an interesting case, in the *Berliner klinische Wochenschrift*, of uremic coma resulting fatally in a person apparently in a fair state of health. A young man, twenty-four years old, a joiner, was admitted into the hospital with sudden symptoms of difficulty of breathing, palpitation, swelling of the feet and ankles, and left-sided headache. His history was that of a feeble childhood, but without any serious illness. His feet had never swelled before, there had been no difficulty with the urine, and he had always been able to attend to his heavy work. He had not been a drinker, had not had syphilis, and had not been a worker in lead, and there was no ascertainable heredity. His face was swollen, his ankles were œdematous, and he was manifestly anemic. The heart was hypertrophied somewhat, the sounds were weak but pure, with no accentuation of the pulmonary or aortic second sound. The pulse was small, regular and without distinct tension. The urine was clear, acid, of the specific gravity of 1.005, with some albumin, hyaline casts and leucocytes. There was nothing abnormal in the internal organs or the blood, but there was albuminuric retinitis. During the first few days of

his treatment at the hospital the subjective symptoms lightened up decidedly, and he expressed himself as feeling quite well and gave the impression of being not seriously ill. The albumin remained at a small amount, and the quantity of urine varied between forty-five and fifty-eight ounces *per diem*, with a specific gravity of from 1.003 to 1.006. Five days after his admission, aphasic symptoms made their appearance as the forerunner of a severe uremic attack, which set in with full force during the night; there were both clonic and tonic convulsions, frothing at the mouth and loss of consciousness. The temperature rose to 103.8° F., the respirations to 60 and the pulse to 160, the cardiac dulness being increased to the right. Death ensued in deep coma from pulmonary œdema. On autopsy, both kidneys were found to be contracted, the right one being somewhat peculiarly displaced, being depressed and lying opposite the fourth and fifth lumbar vertebræ; it was extremely small, not more than two inches long by less than an inch broad, and appeared as a grayish-red fibrous mass with the blood-vessels small and not thickened; from these facts, as well as the microscopic appearances, the condition was judged to be congenital. The case was remarkable as occurring in a young person, without previous uremic symptoms, who was apparently doing well when he fell into a state of profound coma and died in what was, so far as was known, his first seizure.

The Treatment of Burns.

In the Friedrichshain Hospital in Berlin the following is the method of treatment of burns employed by Dr. Bardeleben.

The burned surface is first carefully washed with a two or three per cent. solution of carbolic acid or a three per mille solution of salicylic acid. The blisters are then opened, and the entire surface covered with subnitrate of bismuth finely powdered, and over this a layer of cotton-wool. This dressing is to be renewed as soon as it becomes at all moistened by discharges from the wound. If the burn is very extensive, an ointment of bismuth is substituted for the dry powder.

Dr. Bardeleben asserts that with this dressing cicatrization is much more rapid and suffering much more quickly relieved than is the case with any other form of treatment.

He states that, in spite of the large quantities of bismuth which he has employed, he has never seen any symptoms of poisoning follow its use.—*Therapeutic Gazette*, November, 1890.

Dyspepsia of Children.

The *Annals of Gynecology*, November, 1890, says that according to Jules Simon, dyspepsia is sometimes the early manifestation of a neuropathic state in girls from 6 to 8 years old. The treatment he suggests is:

1. Tonic. General treatment, hydrotherapy, diet and regimen.

2. Sedative. Administer at each meal, well diluted, 3-5 drops of:

℞ Tr. belladonnæ.
Tr. opii camphorat. . . . . āā f℥ss. M.

After the meal prescribe a powder composed of:

Codeiæ . . . . . gr. 1-30 — gr. 1-15
Magnesiæ
Pulv. oculi cancrorum . . . . āā gr. iss
Pulv. rhei . . . . . gr. j
Ext. nucis vomicæ . . . . . gr. 1-6 M.

3. As an eupeptic before meals administer one or two teaspoonfuls of the following, well diluted.

℞ Tr. cascarillæ.
Tr. nucis vomicæ . . . . . āā f℥ij
Tr. rhei . . . . . f℥ss
Tr. aurantii amar.
Tr. gentian. . . . . āā f℥j. M.

Lantanine as Febrifuge.

The *Journal de Médecine*, October 12, 1890, speaks of an alkaloid extracted from the *Lantana Brasiliensis* or *Yerba sagrada*. It is described as a white body, in the form of a fine powder, bitter, presenting alkaloid reactions and forming salts with acids. It exerts a moderating action upon the circulation, like that of quinine, retarding nutrition and lowering temperature. It is employed in intermittent fevers and as an antipyretic. In intermittent fevers it should be administered immediately after a paroxysm. It often succeeds where quinine has failed. The dose is fifteen or thirty grains a day, in pills.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

IMMIGRATION AND PUBLIC HEALTH.

The influence of the enormous immigration which yearly adds hundreds of thousands of human beings to the population of the United States deserves the most careful study of all who are interested in its moral and physical welfare. The economical relations of immigration get a fair share of attention from Congress; but moralists and physicians will have to take the matter up, if the relations spoken of above are to be wisely regulated.

Dr. Hamilton, Surgeon-General of the Marine Hospital Service, has been considering this subject and recommends more rigorous inspection and restriction of immigration.

He suggests that the law be amended so as to provide that hereafter any person intending to immigrate into the United States shall produce to the United States Consul nearest him evidence that he has not been convicted of any crime; that he has not at any time been a public charge in the country where he lives, and that he has not at any time received public assistance. And, further, that he produce to the Consul a certificate from a legally qualified resident physician to the effect that he is at the time suffering from no contagious or chronic disease or disability such as would make him a public charge. This paper should also set forth whether the immigrant intends to become a naturalized citizen or merely a temporary inhabitant. These suggestions cover a good deal of ground, part of it being in the department of political economy. As physicians we are especially interested in the proposition to submit intending immigrants to a strict scrutiny as to their physical soundness, or at least their freedom from grave disease. Just now American experimenters with Koch's "lymph" find it hard to get a subject with lupus to operate upon, and it would be a good thing if the law made it impossible for our European friends to send any of their too numerous lupus afflicted countrymen here. So, it would be well to make leprosy or syphilis and some other diseases which need not be named, a bar to immigration. In this way a certain element of danger to our country would be eliminated from its development and a better chance would be afforded to eradicate certain diseases which have acquired a real, although as yet a slight foothold in this country.

We trust that Dr. Hamilton's suggestion will not be allowed to fall, but that he and the members of the profession generally will try to get it into such shape that Congress can and will act upon it.

TRANSFUSION OF BLOOD AND SALT SOLUTION.

Dr. John Marshall, of the University of Pennsylvania, has published in the *Zeitschrift für Physiologische Chemie*, November 11, 1890, a very interesting article in regard

to the transfusion of a mixture of defibrinated blood and salt solution. After briefly indicating the present position of the question of the use of salt solution in transfusion, he gives an account of a number of experiments, in which he used a mixture of one part of defibrinated blood of the animal on which he had made the experiment, and nine parts of a 6 to 1,000 solution of chloride of sodium. The result of this method of transfusion was exceedingly satisfactory. The results were studied not only as to the general appearance of the animals, but also by careful investigations of the chemical and microscopical conditions of the blood after transfusion. A similar process could be carried out in the case of human beings, of course, using a mixture of human blood with a salt solution. Salt solutions alone are of a recognized value in preserving life after great loss of blood, but the addition of a certain proportion of blood containing living corpuscles, furnishes something besides the mere mechanical distension of the blood-vessels with an innocent circulating fluid, as is the case in transfusion of salt solution alone.

PROPOSED MEDICAL EXAMINERS' BILL FOR PENNSYLVANIA.

At a meeting of the State Medical Society at Pittsburgh, in June, 1890, a Committee on Medical Legislation, consisting of the Presidents of the different County Societies throughout the State, was appointed. This Committee met at Harrisburg, September 17, 1890, and, after consultation, appointed an Executive Committee of seven to draft a proper bill and present it to the meeting of the General Assembly in January.

The bill may not suit each individual member of our profession, but the Committee, after due deliberation, thinks it is the best that we can ask for at this time, and it appeals to the members of our profession in Pennsylvania to give it their support, and see to it that their individual influence is used with their representatives for its passage.

The text of the proposed law will be found in another part of this issue of the REPORTER. We give it for the information of our readers, and hope it will secure their approval and support. Especially do we commend to their notice the intimation of the Committee that it may not exactly suit everybody, and urge that they avoid the risk of losing all by proposing unimportant changes over which disagreement might arise.

The REPORTER thinks this Bill would do much to protect the community, to raise the credit of the State and to elevate the standing of the profession, and will do what it can to secure its passage.

INCORPORATION OF THE PENNSYLVANIA STATE MEDICAL SOCIETY.

On December 20, 1890, the Medical Society of the State of Pennsylvania was incorporated by a decree of the Court of Common Pleas of Philadelphia. This is the outcome of a resolution adopted at the last meeting of the Society, by which a Committee was instructed to secure the incorporation of the Society. It is well that the members of the Society shall understand certain effects of this action. At the next meeting of the Society it will be necessary: 1. To adopt a set of By-Laws (which may be the old ones or any modification of them which may be desired); 2. To fix the date of the annual meeting for the election of Trustees; and, 3. To choose three Trustees to serve for one year, three to serve for two years and three to serve for three years. Each year thereafter three Trustees are to be chosen to take the place of those whose terms expire. The Trustees to act until the meeting of the Society are the members of the present Judicial Council.

The incorporators will be obliged to provide for the perpetuity of the membership by electing such other members as they may see fit—presumably all the present members.

—and providing a method by which hereafter new members shall be chosen.

According to law, the Treasurer will hereafter be compelled to give a bond in such sum, and with such sureties as may be required by the By-Laws for the faithful performance of his duties.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

RECHERCHES CLINIQUES ET THÉRAPEUTIQUES SUR L'EPILEPSIE, L'HYSTÉRIE ET L'IDIOTIE. Compte rendu du service des enfants idiots, épileptiques et arriérés de Bicêtre pendant l'année, 1889.

CLINICAL AND THERAPEUTICAL INVESTIGATIONS OF EPILEPSY, HYSTERIA AND IDIOCY. From the service for idiotic, epileptic and feeble-minded children of the Bicêtre Hospital for the year 1889. By Bourneville, Physician to the Bicêtre; Sollier, Curator of the Museum of the Bicêtre; and A. Pilliet, Former Interne of the Service. Vol. x, 22 wood-cuts and one chromo-lithograph. 8vo, pp. lvi, 188. Paris: Office of the *Progrès Médical*, 1890. Price, five francs.

The first part of the volume before us contains the report proper of the Bicêtre Hospital, with the number of the patients, the classes to which they belong, and the general working of the institution. Following the report are articles on bromide of gold, bromide of camphor, and picrotoxine. The first is believed to have a favorable action on nutrition, and some effect in modifying epileptic seizures. The bromide of camphor acts well in controlling epileptic vertigo. Picrotoxin exerted no favorable influence upon the vertigo. Following these therapeutical papers, Bourneville contributes a very valuable article on "Myxœdematous Idiocy," fully illustrated. Pilliet follows with a paper on "Chronic Encephalitis of Childhood." The histological appearances especially have been studied. The next paper is on "A Family of Hysterical Patients," by Bourneville and Sollier; and, in a concluding paper Bourneville contributes a "Fresh Observation of Myxœdematous Idiocy."

The entire volume will be welcomed most warmly by all neurologists. We sincerely hope that it may be followed by many equally valuable.

AN EPITOME OF TRIPLER'S MANUAL, AND OTHER PUBLICATIONS ON THE EXAMINATION OF RECRUITS. By Charles R. Greenleaf, Major and Surgeon, U. S. A. 8vo, pp. 70. Washington, D. C.: William Ballantyne & Sons, 1890. Price, 75 cents.

Since the publication of Tripler's Manual, much has been written on the general subject of physical examinations, and a number of changes have been announced in such examinations for the United States Army. The author states this fact in the preface to this pamphlet, and says that the recent information on the subject has been incorporated in this "Epitome." The application of the vision-test is explained; instructions for chest measurements are revised, and the subject is in other ways brought up to date.

The Epitome will prove invaluable to recruiting officers, and we can cordially recommend it to all who are interested in physical examinations.

TRANSACTIONS OF THE NEW YORK STATE MEDICAL ASSOCIATION FOR THE YEAR 1889. Volume VI. 8vo, pp. 445. Concord, N. H.: Republican Press Association, 1890.

This volume contains the papers read at the sixth annual meeting of the New York State Medical Association, in New York, September 25–27, 1889. The President's address, by Dr. William T. Lusk, was on Tubal Pregnancy, and is a very able presentation of the subject. In addition to a number of interesting papers, there were two principal subjects of discussion: The Treatment of Hernia, and the New Hypnotics. Speaking of medical operations for the cure of hernia, Dr. Bull said that his sixty-nine cases gave sixty per cent. of cures and forty per cent. of relapses. He prefers the operation of ligation, with excision or drainage of the sac. The discussions upon both subjects were very free and full, and amply justified the wisdom of the Committee on Arrangements in selecting them.

The volume as a whole is a handsome one, and creditable in the highest degree to the Association, and to the Editor, Dr. Edward K. Dunham.

Special Article.

KOCH'S REMEDY FOR TUBERCULOSIS.

A RESUMÉ OF ITS HISTORY.

[*Continued from page 25.*]

The *Wiener Med. Presse*, Dec. 14, 1890, contains the text of the Decree of the Minister of the Interior of Austria regulating the use of the Koch lymph in the Austro-Hungarian Empire. This decree, on the ground that the lymph is a secret remedy with acknowledged dangerous properties, restricts its use to heads of hospitals and scientific medical institutions and physicians authorized to practice in the Empire. It indicates the source from which the lymph must be procured and provides for the making of full records of all cases so treated and the report to the authorities of the circumstances under which any death may take place.

The *Progrès Médical*, Dec. 14, 1890, says that the Germans are becoming more circumspect in regard to the cures—or rather ameliorations—effected with Koch's lymph. It cites from the *Internationale Klinische Rundschau*, Dec. 7, the case of a girl seventeen years old, at Innsbrück, who died after

an injection for lupus of the face. Reaction after injection of 2 milligrams was rapid and marked. The temperature rose to 41.5° (106.7° Fahr.); the respiration became 60; the pulse became imperceptible, and the girl became unconscious and died in 36 hours, with signs of paralysis of the heart. The lymph was obtained from Dr. Libbertz (Koch's authorized agent). Every precaution had been used in diluting it. The autopsy furnished no explanation of the girl's death, which was the more unexpected because she was vigorous and well developed.

In the *Berliner Klinische Wochenschrift*, December 15, 1890, Dr. R. Heinz, of Breslau, publishes a paper on his experimental studies of iodide of potassium and proposes that this salt shall be systematically used in connection with injections of Koch's remedy, because of its apparent power to promote the activity of the leucocytes.

The *Bulletin Médical*, December 17, contains a report of a third lecture by Cornil, in which he speaks, after having used the Koch remedy on thirty patients, as to the temperature change and the variations in the oxyhemoglobin of the blood after its injection. As to the former, he calls attention to the way in which the lymph may seem to delay its action and then suddenly act with exceptional force. The oxyhemoglobin, he finds, diminishes, and for this reason he thinks that the remedy must be used with caution in pulmonary tuberculosis, except in cases in which fever is absent or moderate. He seems to think the remedy may be useful in lupus, but claims very little for it in phthisis.

In the same journal Lannelongue reports using the lymph upon a boy eight years old with lupus of the face. After the third injection he became quite ill; he had a confluent papular eruption and inflammation of the knee, the elbow, the wrist, the shoulder, the hip, and even of the cervical portion of the spinal column. Lannelongue says that if this had occurred after the first injection this would have been claimed to have revealed foci of latent tuberculosis; but as it came on eight days after the first injection it may be asked if it was not due to the action of the lymph setting up new foci of tuberculosis.

The Scotch correspondent of the *Medical Press and Circular*, December 17, 1890, says: "During last week at the Royal Infirmary of Glasgow three cases of lupus were treated with hypodermic injections of Koch's fluid with the following results. In two of the cases so far as curative or other effect was observed they might as well have been injected with cold water, for neither beneficial nor prejudicial effect could be noticed. In the third case there was, to use the cant phrase which is on every person's tongue just now, a decided 'reaction.' The seat of the disease became swollen and congested, and coincident with the subsidence of these effects, and at the present time, the diseased parts certainly look more healthy. The inference drawn in such cases is that lupus is a tubercular disease, that tubercle is due to a microscopic germ termed the tubercle bacillus, and that whatever kills or causes the death of the bacillus, no matter in how roundabout a way, cures the disease; and phthisis pulmonalis as well as lupus consequently. Now it must be pointed out that pathologists are not at all agreed as to lupus being a tubercular disease, and it does not necessarily follow that if a remedy is found for lupus that the dreadful scourge of consumption would be equally amenable to the same influence. Here in three cases of lupus under the observation of the writer, but one of them responded to the Koch fluid, and it would be premature to say as yet that the disease is either arrested or cured in this one case. Again, most men of any experience in practice have occasionally experienced gratifying results in the treatment of certain cases of lupus, from well-known and ancient remedies of the pharmacopœia. The writer has cured cases of lupus more than twenty years ago, in the sense in which lupus is now said to be cured, by combinations of bichloride of mercury, iodide of potassium and arsenic (Donovan's solution), and he entertains the opinion that the hypodermic injection of these substances in proper quantity would yield results not inferior to those of Koch's fluid, so inordinately and so injudiciously vaunted. The French have had most favorable results with hypodermic injections of iodoform dissolved in olive oil. It is not a little significant in this relation that Billroth, of Vienna, a gentleman of acknowledged eminence throughout Europe, has expressed the opinion that as a curative agent in lupus iodide of potassium is superior to 'Koch's lymph.' In the case of the phthisical cases treated in the Royal Infirmary of Glasgow, a trifling reaction took place in one or two of them, that is to say, the temperature rose considerably, but so far as amelioration of the urgent symp-

toms was concerned, this existed only in the luxuriant imagination of the sanguine converts to the new doctrine. In other cases of undoubted phthisis no result whatever ensued."

The same journal says: "If Koch's lymph is scarce at Berlin it is abundant at Davos Platz, where the arrival of some twenty-five phials was announced a few days since, being enough to treat a thousand patients for a couple of months! Consumptive patients at Davos, however, probably feel pretty comfortable, for only about a hundred of the fourteen hundred tuberculosis residents elected to undergo the treatment, the others preferring to run the risk of having to attend the funerals of those to be experimented upon."

In the New York *Medical Record*, Dec. 27, 1890, there is an article by Dr. H. P. Loomis, describing his trip to Berlin to get lymph for the Bellevue Hospital, and his observations and opinions. He has apparently been very much impressed by what he saw. Under the head of "Conclusions" he says: "If I were asked to express an opinion as to the efficacy of the new remedy, I should say I believe it to be as great a medical discovery as that made by Jenner; that it opens up a hitherto unknown field in the treatment of disease, which no one at the present time can limit; that it apparently cures lupus, as admitted by all observers. (!)" With regard to its curative power in pulmonary tuberculosis, he quotes the answers made to a series of questions he addressed to Prof. Leyden a few days before leaving Berlin. The substance of the answers is that Prof. Leyden has noticed *permanent* improvement in some cases of early phthisis following the use of the remedy, but thinks time can alone show how frequent such cases are; that he has seen improvement in some advanced cases; that he would use the remedy on his own child; that he favors its use in private practice; that he has seen disastrous effects following its use in unsuitable cases and in overdoses; that as a precaution he would administer small doses, beginning with from 1 to 5 milligrams;[1] that he continues constitutional treatment while using the remedy; and that it has no *positive* diagnostic value in all cases.

In New York experimentation with the lymph continues.

At St. Francis Hospital, December 24, Dr. George F. Shrady inoculated seven cases, two for tubercular disease of knee-joint; one for tubercular caries of wrist-joint; one for carious sinus of thigh; one for scrofulous sinus of groin; one case of incipient phthisis, and one case of phthisis in second stage. The latter was a patient of Dr. John H. Ripley. The inoculations were prepared under the supervision of Drs. Max Einhorn and E. C. Wendt, and according to the strict Berlin method.

The *Medical Record*, December 27, says that, in a general way it may be said that no new features have been developed. The reactions in the phthisis cases have been quite constant, as also in the cases of lupus, the latter having been reported as improving. The doses have generally been one milligram, which has been cautiously increased in accordance with the amount of reaction produced. As yet no accidents nor serious complications have occurred in connection with the inoculations; neither has there been any death attributable to their use.

Notes and Comments.

Proposed Act for Medical Examiners for Pennsylvania.

An Act to regulate the Practice of Medicine and Surgery, to establish a State Board of Medical Examiners and Licensers, to define the powers and duties of such Board, the qualifications of applicants for license, the manner of licensing, and making an appropriation for said Board.

Whereas, The safety of the public is endangered by incompetent physicians and surgeons, and due regard for public health and the preservation of human life demands that none but competent and properly qualified physicians and surgeons shall be allowed to practice their profession:

Section 1. Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met, and it is hereby enacted by authority of the same, that within one month after the passage of this Act the Governor shall appoint a State Board of Medical Examiners and Licensers consisting of nine members, three to serve for one year, three for two years, and three for three years in the first instance, and thereafter annually

[1] A dose of 2 milligrams killed the girl at Innsbrück, spoken of above.—Ed. Reporter.

the Governor shall appoint three members to serve for three years in place of those whose terms then expire. The said persons so appointed shall be graduates of some legally-chartered college or university having the power to confer medical degrees, citizens of the United States and of this Commonwealth who shall have been in the active practice of medicine or surgery for a period of not less than ten years, but no two of whom shall be residents of the same county.[1] Each member of the said Board shall receive a certificate of appointment from the Govenor, and shall file the same within twenty days with the Prothonotary of the Court of Common Pleas of the county in which said member is registered under existing law.

SECT. 2. The said Board shall be known by the name and style of the State Board of Medical Examiners and Licensers of the Commonwealth of Pennsylvania, and shall have a common seal, and may make and adopt all necessary rules and regulations and by-laws not inconsistent with the Constitution and laws of this Commonwealth, or of the United States, and shall have power to locate and maintain an office within this State for the transaction of business. Five members of the said Board shall constitute a quorum for the transaction of business.

SECT. 3. Every appointment to fill a vacancy or vacancies in the said Board shall be for the unexpired term, and the said vacancy or vacancies shall be filled by the Governor within sixty days after notification of the same by the Board, and he shall have power to remove any member of said Board for criminal, scandalous, or dishonorable conduct.

SECT. 4. The said Board shall organize at Harrisburg within three months from the date of their (its) appointment, and shall elect from its own number a President and Secretary who shall also act as Treasurer, both of whom shall hold their offices for one year, or until their successors are chosen.

SECT. 5. The members of the said Board shall each receive a salary not exceeding three hundred dollars per annum, to be paid out of the fees for examination. The Secretary-Treasurer shall receive an additional salary to be fixed by the Board, and shall file with the President of the Board a bond in the sum of one thousand dollars, conditioned for the faithful performance of his duties. The necessary expenses of the said Board shall also be paid out of the fees, except as provided in Section 12 of this Act, and any balance remaining from the fees, after the disbursements herein specified, shall be paid into the treasury of the Commonwealth.

SECT. 6. The said Board shall examine all applicants for license to practice medicine or surgery in this Commonwealth who are properly qualified according to the provisions of Section 7 of this Act, and no one shall be excluded or rejected on account of adherence to any special system or school of practice. It shall hold two stated meetings in each year, one at Pittsburg on the first Tuesday of April, and one at Philadelphia on the first Tuesday of May respectively, and may hold special meetings at such times and places as it may deem proper. All examinations, when practicable, shall be conducted in writing, and all examination papers, together with the reports and action of the examiners thereon, shall be preserved among the records of the said Board for a period of five years, during which time they shall remain open for inspection at the office of the said Board.

The applicants shall be examined in anatomy, physiology, chemistry, toxicology, pathology, hygiene, materia medica, and therapeutics, principles and practice of medicine, surgery, and obstetrics, and each applicant upon receiving from the Secretary of the Board an order for examination shall draw by lot a confidential number, which he or she shall place upon his or her examination paper, so that when said papers are passed upon by the Examiners the latter shall not know by what applicant said papers have been prepared, and upon each day of examination all candidates shall be given the same set of questions. *Provided* that any candidate for examination may elect the system of materia medica and therapeutics in which he or she shall be examined.

SECT. 7. Any person on paying twenty dollars to the Secretary of said Board, and on presenting satisfactory proof of being over twenty-one years of age, of good moral character, and of having received a sufficient preliminary education, as defined by said Board, and a diploma from some legally-incorporated medical college or university having authority to confer degrees in medicine, shall be entitled to examination by the said Board, and in case of failure at any examination shall have the privilege of sub-

[1] And none of whom shall be member of the faculty or staff of any medical school or university.

sequent examinations without the payment of an additional fee. Each applicant who shall have passed a satisfactory examination shall receive from the said Board, under seal, a license to practice medicine and surgery in the Commonwealth of Pennsylvania, and the said Board may at its discretion grant licenses without examination to persons holding licenses from similarly-constituted boards of examiners or boards of health in other States.

SECT. 8. The Secretary shall record in a book to be kept for this purpose in the office of the said Board, the name, age, sex, residence, date, and place of examination, the examination number, the examination average on each branch, the general average, and date of issue of license, in case such license is granted. Said book shall be open to public inspection, and on or before the last day of December of each year the said Board shall publish, or cause to be published, a list of the names and addresses of such persons as shall have received licenses from the said Board within twelve months immediately thereto preceding.

SECT. 9. After the first day of July, Anno Domini one thousand eight hundred and ninety-one, no person shall enter upon the practice of medicine or surgery in the State of Pennsylvania unless he or she has complied with the provisions of this Act, and shall have exhibited to the Prothonotary of the Court of Common Pleas of the county in which he she desires to practice medicine or surgery, a license duly granted to him or her by the said State Board of Examiners and Licensers, whereupon he or she shall be entitled, upon payment of one dollar, to be duly registered in the office of the Prothonotary of the Court of Common Pleas in said county, and any person violating any of the provisions of this Act shall be guilty of a misdemeanor, and upon conviction thereof in the Court of Quarter Sessions of the county where the offence shall have been committed, shall pay a fine of not less than one hundred dollars nor more than five hundred dollars for each offence, one-half of which fine shall be paid to the prosecutor.

SECT. 10. Nothing in this Act shall apply to commissioned medical officers of the United States Army or Navy, or of the United States Marine Hospital Service, nor to any member of the house or resident staff of any legally-chartered medical college or university or hospital during his term of service therein, nor physicians of other States meeting duly registered physicians in this State in consultation, nor to those practicing dentistry exclusively. And nothing in this Act shall be construed to prohibit the practice of medicine and surgery within this Commonwealth by any practitioner who shall have been duly registered before the first day of July, Anno Domini one thousand eight hundred and ninety-one, according to the terms of the Act entitled "An Act to provide for the registration of all practitioners in medicine and surgery," approved the eighth day of June, Anno Domini one thousand eight hundred and eighty-one.

SECT. 11. For the purpose of this Act, the words "practice," "medicine" or "surgery" shall mean to treat, operate on or prescribe for any physicial ailment of another. But nothing in this Act shall be construed to prohibit service in cases of emergency or the domestic administration of family remedies.

SECT. 12. The sum of one thousand dollars, or so much thereof as may be necessary, is hereby appropriated to meet the necessary and legitimate expenses of the said Board for the year Anno Domini one thousand eight hundred and ninety-one.

SECT. 13. All Acts or parts of Acts of Assembly inconsistent herewith shall be and are hereby repealed.

Medical and Surgical College of New Jersey.

The District Medical Society for the County of Hudson, N. J., recently adopted the following preambles and resolutions:

WHEREAS: A certain medical institute, called the "Medical and Surgical College of the State of New Jersey," chartered by special Act of this State, approved March 17, 1870, was organized during the year 1888, and opened in three small rooms on the top floor of the general office building, No. 47 Montgomery street, Jersey City; and

WHEREAS, Said alleged college has graduated several students whose diplomas have been presented to the Hudson County Board of Health, and who have been refused registration; and

WHEREAS, It has appeared to this Society, by good and sufficient evidence, that several members of the faculty, nearly all of whom are non-residents of this State, are either incompetent to deliver lectures on the topics assigned them, or are graduates of

disreputable or fraudulent medical colleges; that the facilities for instruction in said alleged college are totally inadequate, and that no clinics, dissections or hospital practice have been or can be given; that the provisions of the charter of said college have not been observed by the authorities thereof; that the requirements of said charter, even if the same were strictly followed, are far below the standard of minimum requirements of medical colleges adopted and demanded by all medical authorities at the present time, and that, therefore, the possession of a diploma from said alleged college is no proof whatever that the holder thereof has received a good and sufficient medical education; and

WHEREAS, The State Board of Medical Examiners of this State will introduce a bill at the next meeting of the Legislature for the purpose of repealing said charter:

Be it Resolved, That the District Medical Society for the County of Hudson does hereby earnestly protest against the existence of said alleged college as an unnecessary, inadequate and disreputable institution, tending to degrade and lower the standard of the medical profession; that the influence of this Society and of the individual members thereof be given to the support and passage of the bill to repeal said charter, and that a copy of this resolution be forwarded to the several medical societies of this State with requests for their support and influence for the passage of said bill.

These resolutions are attested by Henry B. Rue, M. D., Secretary, Jersey City, N. J., December 16, 1890.

[As the REPORTER exposed the methods of this "college" in an Editorial, August 24, 1889, it will be understood that we find no hesitation in supporting the purpose of the Hudson County Society and of the New Jersey State Board of Medical Examiners. It will be a good work if this Board can get the State freed from the institution which now bears its name.]

Dilatation for Dysmenorrhœa.

In the *Weekly Medical Review*, December 6, 1890, Dr. Paul J. Barcus, adopting largely the views of Dr. W. G. Wylie, of New York, makes a plea for rapid dilatation of the cervix uteri for dysmenorrhœa. Of the mode of carrying out rapid dilatation, he says that care in the selection of cases is not the only essential to successful treatment. The operation must be carried out in detail, and attention must be equally directed to the after-treatment, both constitutional and local. The proper time for operating is about one week after a menstrual period, which will allow sufficient time for the lacerated mucous membrane to recover before the next period. Before commencing, all peri-uterine tenderness must be subdued, as it gives no promise of good results if there is pelvic peritonitis or cellulitis, or any degree of inflammatory process in the adnexa. With these conditions present it becomes an operation fraught with great danger to the life of the patient. Endometritis or metritis without implication of the surrounding tissues, or flexions or versions do not contra-indicate.

A bivalve dilator should be used. The patient should be anæsthetized, the blades should be introduced closed up to the shoulder, and should engage the internal os sufficiently to dilate it without slipping. The blades should be slowly and carefully spread to the extent of three-quarters or one inch and allowed to remain so for several minutes, care being taken to avoid slipping of the expanded blades out of the cervix, and consequent laceration of its tissues. The dilators being then removed, a hollow, hard-rubber stem should be introduced, one of sufficient length to engage the fibers of the internal os (about two and a quarter inches), and sufficiently large to maintain dilatation to some degree, and tapering from the point, the better to insure its retention. This should be supported for from twenty-four to forty-eight hours by a cotton tampon saturated with boroglyceride, by which time the fibers of the internal os will have contracted down upon the stem sufficiently to retain it in its place, without the assistance of the tampon. If the stem causes any degree of irritation it should be removed, to be reinserted when all irritation has subsided. But it will be found that but few patients will complain of it, and many will be ignorant of its presence if not so informed.

The patient should be kept in the recumbent position for four or five days, or until the immediate effects of the operation have subsided. If there is no obstruction of the stem, and it causes no inconvenience, it may be left in position during the next sickness. Ordinarily it should be removed before, to be reinserted again. The use of the stem obviates the necessity for using intra-vaginal pessaries, and for repeating the dilatation;

serves to correct the position of the uterus; and its presence within the canal and body of the organ seems to exert a therapeutic effect upon the mucous membrane and nerves distributed to those parts, and upon the nutrition and functions of the organ itself, that can hardly be accounted for by the better drainage and corrected position alone.

The condition of the patient is such that the constitutional treatment must be carried on at the same time, and with equal care. Most cases require a course of general tonics, and especial care as to the usual influence brought to bear upon the mind of the patient. They do better when removed from the sympathetic watchfulness of friends and relatives.

By carrying out this method of treatment but few cases will be found that cannot be relieved. Dr. Barcus's experience in the past convinces him that the large majority of so-called intractable cases are obstinate because of the imperfect manner in which the treatment has been executed.

Testing Water.

Among the scraps of erroneous information which appear in scientific journals with more or less regularity, is one about testing the purity of water by the addition of a little pure sugar. It is said that when water is so treated, any organic matter present is after a time discovered in the form of black specks floating in the liquid.

This scrap is on its rounds again, having possibly made a transatlantic journey since its last appearance here, and the method referred to is now credited to a professor in a Western university.

The truth about the matter, as has before been stated in this journal, is that the test referred to was originally proposed by Heisch for the detection of a fungus supposed to be peculiar to sewage. Pure sugar was added to the suspected water in the proportion of about half a gram to 100 cubic centimeters in a stoppered bottle, and the bottle being placed in a strong light was kept at a temperature of 80° F. for several hours. It was then examined for the fungus, which if present was disclosed as a distinct turbidity to the naked eye, and under a power of 250 diameters was found to consist of small spherical cells. Heisch believed that the cells thus developed were distinct evidence that the water was contaminated with sewage, but Frankland showed that the spores of this particular fungus were present in all waters that had been exposed even momentarily to the air, and that their development was due simply to the presence of phosphates in the water. The addition of even a minute trace of any phosphate was sufficient to develop the fungus in any water under the conditions above stated.

From this it will easily be seen that the so-called sugar test is not only of no value for the purpose for which it was recommended, but is positively misleading, and consequently dangerous.

It ought to be well understood that there is no "handy" test for the purity of water. It is sometimes easy enough to show very promptly that a given water is unfit for drinking, but to make sure of its safety is quite another matter.

It is very evident that the dissemination of misinformation on such a subject is calculated to do much harm, and those who are concerned with preserving health should not fail to show, whenever opportunity offers, the danger of forming conclusions as to the purity of water by "popular" or easy tests.—*Druggists' Circular*, December, 1890.

Guaiac as a Purgative.

Dr. William Murrell, Lecturer on Pharmacology at Westminster Hospital, says in the *Medical Press*, Nov. 5, 1890:

In our thirst for new remedies there seems to be a danger that some of our good old-fashioned drugs may be forgotten. Take guaiacum for example. In most of our text-books on materia medica we are told that guaiacum resin acts as "a stimulant, diaphoretic and diuretic." I cannot find that there is much evidence in support of this view. Wood, of Philadelphia, seems to be of the same opinion, for he says: "Guaiacum is believed by some to act as a diaphoretic, and to do good by increasing the elimination of the skin, but as I have not been able to obtain either from medical literature or from the exhibition of the medicine any distinctive proof of its having any such action to any marked extent, I have preferred to consider the drug as an alterative." Schmiedeberg, of Strassburg, curiously enough deals with it under the head of "Drugs and preparations used for all sorts of purposes but now mostly antiquated and obsolete." I am inclined to think that its main action is as a laxative or purgative, and this view is evidently shared by Dr. C.

D. F. Phillips, who, in his well-known work on the *Vegetable Kingdom*, states that in large doses it produces "dryness in the mouth, burning in the throat, a sensation of heat in the stomach, loss of appetite, heartburn, flatulence, nausea, vomiting and purging." My attention was drawn to the subject some two years ago by casually prescribing for a city man suffering from rheumatism some guaiacum lozenges made up with black currant paste. He continued taking them long after the pains had ceased, and his explanation was that they did him good by acting on the liver and bowels. He said that one or two of the lozenges taken in the morning before breakfast acted promptly and without inconvenience. I ordered the lozenges for other of my patients suffering from constipation, and what is conventionally called "biliousness," and the result was equally satisfactory. The lozenges not being available for hospital use I had a confection prepared containing ten grains of guaiac resin to a drachm of honey. This was curiously popular with the patients, and for the last two years I have used it extensively not only as a purgative but in the treatment of chronic rheumatism, sciatica, tonsillitis, dysmenorrhœa and allied affections. The confection is nasty, but is appreciated by patients. At first I gave it in drachm doses once a day, but they were not satisfied with this and I had to increase the dose to two drachms three times a day. In this quantity it seems capable of producing the maximum of inconvenience and discomfort, and gives unlimited satisfaction. The purgative effect is very pronounced, and in one case the patient had fifty-six evacuations in the week. In another case it produced a well-marked rash, covering the arms and legs with an eruption which forcibly reminded one of copaiba. That this rash is rare may be gathered from the fact that my colleague, Dr. C. T. Fox, had seen only one similar instance. It was accompanied by intense itching which disappeared on discontinuing the drug. The guaiacum not infrequently gives rise to a burning sensation in the throat, and to obviate this I prescribed the ten grains of the resin in half an ounce of extract of malt, which answered admirably. This method of treatment is, perhaps, simply a return to the old-fashioned "Chelsea Pensioner," which consisted of guaiacum, rhubarb, ginger, sulphur and certain other ingredients, but it is interesting nevertheless. I am sure that a trial of the guaiacum resin as a laxative or purgative, according to the dose employed, will be found satisfactory. It is possible that if the drug were triturated with cream of tartar, sugar of milk, or some other equally inert substance, its efficacy would be increased, and it would produce the desired effect in smaller doses.

Death from Injection into the Lung.

Dr. Robert T. French, of Rochester, N. Y., reports in the *Medical News*, Nov. 29, 1890, the following mishap, occurring in the treatment of phthisis by intra-pulmonary injection, is interesting. During part of the writer's term of service as house physician of the Buffalo General Hospital in 1888–89, a large number of cases of phthisis were treated by intra-pulmonary injections. The medicament used was a three-per-cent. solution of beechwood creasote in oil of sweet almonds. Of this about ten minims were injected at a time into a cavity or solidified apex. In most instances the immediate effects were very encouraging. The expectoration usually decreased, and the temperature, after the slight rise caused by the operation, fell, and continued for a time nearly normal. More than fifty such injections had been made with favorable results, when the following accident occurred.

The patient was well nourished, and under tonic treatment, and the disease seemed to be in abeyance. Three injections had been made, at intervals of four days, into the left apex, followed in each instance by decreased expectoration and marked diminution of evening temperature. The fourth injection was made by the usual method into the right apex, and the patient immediately after the procedure resumed his duties about the ward. Twenty minutes later he was seized with violent dyspnœa, which gradually became worse. He had formerly suffered from asthma, and the present attack resembled an asthmatic paroxysm. The irritation caused by the drug on the peripheral endings of the vagus seemed to afford a plausible explanation in support of this diagnosis. The usual remedies for asthma were administered, but all failed to give relief. Auscultation was rendered impossible by the violent tossing and groaning of the sufferer. About an hour and a half after the injection the patient died.

At the autopsy the right lung was found entirely collapsed and the pleural cavity

filled with air. The needle in entering the lung had passed through tissue as thin as ordinary writing-paper into an emphysematous space, communicating with a small cavity, which in turn communicated with a bronchus. After the puncture the thinness of the wall prevented it from retracting sufficiently to act as a valve, and the inspired air must have passed almost directly into the pleural cavity.

Cases of pneumo-thorax have been reported, following intra-pulmonary injection; but all were slight, and ended in recovery. Only one death immediately following this treatment is recorded, and in that case death was due to acute suppurative bronchitis. Had the pneumo-thorax been diagnosed in Dr. French's case at the outset of the attack he thinks it is possible that surgical interference might have saved the patient. The condition, however, was wholly unexpected, and was not recognized by any of the physicians who examined the case.

The slight benefits following this method of treatment are, in Dr. French's opinion, secured at too great a risk to make the procedure advisable.

Hypodermic Use of Strychnia.

Dr. Harold N. Moyer, of Chicago, in a paper read before the Southern Surgical and Gynecological Association, at Atlanta, claimed that the irritating properties of Fowler's solution, when injected into the cellular tissue, were largely due to the presence of free arsenious acid. This objection to the hypodermic use of the drug had been obviated by employing a solution of the arseniate of sodium, a stable, neutral salt of definite composition. This salt could, he found, be injected beneath the skin without causing more irritation than would be produced by so much water. He confirmed Hammond's conclusions that arsenic was less poisonous when given by the hypodermic method than when employed by the mouth. He had had a similar experience, in administration of the drug by the mouth, to the utmost limit of toleration, until the eyes were reddened and the stomach disturbed. Then the use of the drug by the mouth was suspended, and an increased dose given hypodermically, with complete subsidence of the poisonous symptoms. The toxic properties of arsenic are largely focused upon the stomach, liver and upper end of the small intestine. If we administer arsenic by the cellular tissue it immediately enters the general circulation and so avoids the selective action that the liver undoubtedly possesses for metallic salts. An analogous example was to be found in the use of mercuric salts, by inunction and injection.—*Weekly Medical Review*, December 6, 1890.

Tannic Acid as an Intestinal Antiseptic Remedy.

Professor Cantani has written, in the *Wiener medizinische Blätter*, of his therapeutical trials of tannic acid in intestinal diseases. He has found it, in ⅓, ½, or even in 1-per cent. solutions, acting a useful part as an antiseptic, as it hinders the vegetative activity of the microbes and renders innocuous many of the poisonous ptomaines. In diarrhœa and dysentery, therefore, tannic acid becomes an important disinfectant as well as astringent remedy. Mosler also reports that this drug is very beneficial in typhoid fever, particularly for removing the symptoms of meteorism and diarrhœa. Antiseptic solutions are best introduced by enteroclysis [injections into the colon], the fluid thus administered having been proved, by the subsequent vomiting of some of it, to reach not only the whole length of the intestines, but even to the stomach.—*New York Medical Journal*, December 6, 1890.

NEWS.

—Dr. W. H. Elliot, of Houston, Texas, died December 23, 1890.

—Prof. Hyrtl, the Austrian anatomist, celebrated his eightieth birthday recently.

—Dr. C. H. Hall, of Boston, was arrested for alleged malpractice December 29, 1890.

—The new St. Christopher's Hospital, in Philadelphia, was opened December 29, 1890.

—Dr. George P. Wesselhœft, a well-known physician of Brookline, Mass., died December 29, 1890.

—H. A. Kelso, of Paxton, Ill., was assaulted and robbed in Chicago, on December 19, 1890. His skull was fractured.

—Dr. A. F. Holt, Surgeon-General of Massachusetts, died in Florida, December 28, 1890. He was fifty-two years old.

—Dr. John B. Hayes, a well-known physician of New York, was attacked by a highwayman, while walking through Union Square, early New Year's morning.

—A death under ether anæsthesia occurred in the St. Barnabas Hospital, Minneapolis, December 25, 1890. The patient was a well-built young man, with a tumor of the foot.

—Dr. Nathaniel R. Boutille, of Coatesville, Me., died December 22, 1890, of paralysis. He was almost seventy years old, and was a highly-esteemed citizen and practitioner.

—The American Chemical Society, at its concluding session in Philadelphia, December 30, took steps towards uniting with other bodies of chemists in the formation of a national organization.

—Dr. Theron Temple, of Waltham, Mass., died December 28, 1890, at the age of 57, after a long sickness. He had been city physician of Waltham and for several years in the Boston Custom House.

—Dr. Nicholas Senn in December resigned his Professorship of Surgery at the Rush Medical College, Chicago. The reason assigned is the refusal of Prof. Parker to permit Prof. Senn to deliver clinical lectures at the college.

—It is reported that physicians have been sent by the Russian government to Asia Minor to test by experiment the treatment of cholera with the ferubia sumbul, a plant growing in Turkestan and possessing antispasmodic properties.

—Dr Samuel G. Dixon, the bacteriologist of the American Academy of Natural Sciences, returned December 29, 1890, from Berlin, where he had been studying the merits of the Koch lymph on behalf of the Jefferson Medical College.

— Mr. John Ogden has associated with him Mr. W. S. Harvey as a partner in the drug business, conducted at Walnut and 13th streets and Arch and 19th streets, Philadelphia. Both stores will be conducted under the firm name of John Ogden & Co.

—A dispensary for the treatment of the diseases of women amenable to electricity has been opened at 1632 Cherry St., Philadelphia, under the charge of Dr. G. Betton Massey and Dr. Horatio R. Bigelow. Physicians are invited to bring or to send suitable cases on Mondays, Wednesdays or Fridays at 3 P. M.

—Dr. Edgar M. Green, of Easton, Pa., who was recently engaged to make certain chemical and microscopical investigations for the Court at that place, presented a bill for $200 for his services. The County Commissioners refused to pay the bill, but agreed to abide by an arbitration. The arbiters decided in favor of Dr. Green and said the bill was reasonable.

—The advent of the new year in Norristown was marked by the formal opening of the borough's first charity, Charity Hospital, which was then turned over to the public for its first inspection. It is claimed by the directors of the concern that it has more cubic inches of space per bed than any other charity hospital in the State.

—The new building of the Polyclinic Hospital, on Lombard street, above Eighteenth, Philadelphia, was opened for the reception of patients December 29, 1890. All the clinics were opened in the morning with their apparatus in full working order. The wards are not yet ready for the reception of patients, but are expected to be ready in about a week.

—According to the Bureau of Vital Statistics the health of New York, in 1890, was better than in 1889, as the death-rate was 24.66 per 1,000, against 25 last year. This calculation, however, is based on an estimated population of 1,631,232. There were 40,230 deaths in the city during 1890, or an average of one in every 13 minutes during the year. In 1889 the deaths were 39,583. There were 39,250 births and 14,992 marriages. Over one-fourth of all the deaths were of children under 1 year old. Phthisis and pneumonia were the chief causes of death, they being responsible for 10,418 of the deaths. There were only two fatal cases of small-pox.

OBITUARY.

L. M. HUBER, M. D.

Dr. Lee Huber died in Rocky Ford, Col., December 18, 1890. He was born in 1853 in Lancaster Co., Pa., and was graduated in 1877 from the Millersville State Normal School, of his native State. Some time after that he received a degree from Lafayette College. In the fall of 1882, he entered Jefferson Medical College, of Philadelphia, and in 1884 was graduated from that College, taking the first prize in obstetrics. He then located and entered into a promising practice in Chicago, but his health failing him, he moved to the far West, where his life was terminated by consumption.

He was a contributor to the MEDICAL AND SURGICAL REPORTER, whose papers were always interesting and instructive.

"This is an Age of Apollinaris Water."
—Walter Besant.

Apollinaris

"THE QUEEN OF TABLE WATERS."

"Familiar in millions of mouths as any household word.

"The popularity of Apollinaris Water is chiefly due to its irreproachable character.

"More wholesome than any aerated water which art can supply."—THE TIMES, LONDON.

"Of late years the Queen, by the advice of Sir William Jenner, has usually taken Apollinaris Water.—THE WORLD, LONDON.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonary Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

SCOTT'S EMULSION

VERSUS

PLAIN COD LIVER OIL.

Plain Cod Liver Oil ***is indigestible, deranges the stomach, destroys the appetite is not assimilated,*** and in a majority of cases is detrimental to the patient.

SCOTT'S EMULSION

Can be ***digested in nearly all cases, is assimilated, does not derange the stomach, nor overtax the digestive functions,*** and can be taken for an indefinite period when the plain cod liver oil cannot be tolerated at all, and with most marked results in ***Anæmia, Consumption*** and all wasting conditions. It also contains the ***Hypophosphites of Lime and Soda with Glycerine,*** which are most desirable adjuncts.

WHEN PHYSICIANS TRY IT THEY INVARIABLY USE IT

in preference to the plain cod liver oil or other ***so-called Emulsions*** that invariably separate, and hence their integrity and value is destroyed. ***Scott's Emulsion is palatable and absolutely permanent*** hence its integrity is always preserved.

The formula for SCOTT'S EMULSION is 50 per cent. of the finest Norwegian Cod Liver Oil, 6 grains Hypophosphite of Lime and 3 grains Hypophosphite of Soda to the fluid ounce, Emulsified, or digested to the condition of assimilation with chemically pure Glycerine and Mucilage.

We also wish to call your attention to the following preparations:

CHERRY MALT PHOSPHITES.

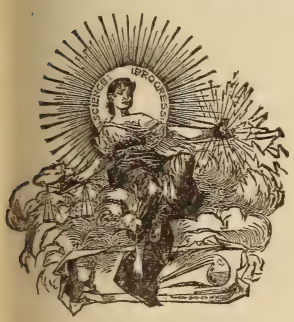
A combination of the tonic principles of Prunus Virginiana, Malted Barley, Hypophosphites of Lime and Soda, and Fruit Juices. An elegant and efficient brain aud nerve tonic.

BUCKTHORN CORDIAL (Rhamnus Frangula).

Prepared from carefully selected German Buckthorn Bark, Juglans Bark and Aromatics. The undoubted remedy for Habitual Constipation.

Be sure and send for samples of the above—delivered free.

SCOTT & BOWNE, 132 South Fifth Avenue, NEW YORK.



CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (ABSOLUTELY HARMLESS.)

Is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT,
AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. Geo. B. Hope, Surgeon Metropolitan Throat Hospital, Professor Diseases of Throat, University of Vermont, writes in an article headed, "Some Clinical Features of Diphtheria, and the treatment by Peroxide of Hydrogen" (*N. Y. Medical Record*, October 13, 1888). Extract:

". . . On account of their poisonous or irritant nature the active germicides have a utility limited particularly to surface or open wound applications, and their free use in reaching diphtheritic formations in the mouth or throat, particularly in children, is, unfortunately, not within the range of systematic treatment. In Peroxide of Hydrogen, however, it is confidently believed will be found, if not a specific, at least the most efficient topical agent in destroying the contagious element and limiting the spread of its formation, and at the same time a remedy which may be employed in the most thorough manner without dread of producing any vicious constitutional effect. . . .

"Inasmuch as the efficacy depends upon the ozonized oxygen in solution, it has seemed desirable to rely on the full strength of the officinal preparation of fifteen volumes, especially when used in the fauces, where any slight irritation from its acidity is not apparent. In all the cases treated (at the Metropolitan Throat Hospital), a fresh, standard Marchand preparation of fifteen volumes was that on which the experience of the writer has been based. . .

"An equally important element is in making the application in such a manner as to produce the most determined effect on the diseased tissues with as little local disturbance as possible. . . . A steady, coarse spray, with an air pressure of twenty pounds or more, will, in a few moments' time, produce a more positive action than prolonged efforts to reach the fauces by means of cotton applicators. . . . How frequently the treatment is to be followed up depends to a considerable extent on the density, as well as the area, of the surface involved. . "

CAUTION.—By specifying in your prescriptions "**Ch. Marchand's Peroxide of Hydrogen** (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label aud signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

A book containing full explanations concerning the therapeutical applications of both CH. MARCHAND'S PEROXIDE OF HYDROGEN (Medicinal) and GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

A CASE WITH A LESSON IN IT.

We have frequently referred to the necessity of keeping the pregnant woman supplied with those chemical substances which she must give to the child in the formation of its little frame, and the dire effects which may result from a deficiency of those substances. The headaches, neuralgias, spinal tenderness, and some of the many disorders of digestion, and even mental failure, may be all prevented or relieved by supplying to the mother the chemical food her system demands.

We have noticed a few cases where the most serious results have occurred to the mother by such a deficiency, one of which is well worth relating. Mrs. M., aged 30, pregnant with her third child, suffered from the second to the fifth month of her pregnant term with gradually failing strength and health, and nervous irritability. She was very restless nights for three or four days, the peculiar restlessness of complete nervous exhaustion, and was irrational for more than a week.

At this time I advised that she have a teaspoonful of Murdock's Liquid Food every hour in milk, and a little wine every four hours. The third night she had fifteen drops of hydrobromic acid dil. every three or four hours, which was continued for a week. The liquid food after a week every two hours, and all other medicines were discontinued. Her bowels were moved with a mild laxative at first, and afterward became regular. Her tongue cleaned quickly and her skin assumed a more natural appearance.

At this writing, less than three weeks from our first visit, the patient is able to sit up an hour at a time, is quite rational and cheerful, has a good appetite, the bowels are quite regular, there is no headache, and but little spinal tenderness. She sleeps reasonably well if fed frequently. She is allowed to suit her taste in her diet. The child is quite active, and the mother is progressing so nicely that it is hoped that she will pass safely through her confinement, which is nearly at hand. She will be kept on the liquid food and the phosphates until her confinement after which, the condition will suggest the treatment. This is the most marked case of a starved nervous system we have ever seen, and the benefit derived from the treatment proves the theory as to the cause of the trouble.

Apropos with the above, comes the question of the selection of nutritious foods for those many cases which demand strong and immediate nourishment. The food used in the above case has produced marvelous results for us in some of those extreme cases in which we have used it.

In one case of nervous exhaustion the insomnia was absolutely painful. When the exhaustion forced the patient to sleep there was an immediate sense of falling or approaching death, or there were hallucinations which were appalling, rendering the nights unbearable. One teaspoonful of Murdock's Liquid Food so nourished the system the first night it was given that the patient sank into a quiet, refreshing sleep which lasted, with a single awakening, until morning, and the improvement the patient obtained was most striking.

One case of mitral regurgitation with leucocythemia and nervous exhaustion improved more rapidly on this food than on all other measures combined. In cases of nervous exhaustion and brain tire, its effects are most marked, as we have experienced many times in the past five years in the frequent personal use of the agent. It contains the principles of pure, healthy blood and nerve tissue ready for immediate assimilation. Fourteen per cent. of the entire quantity is uncoagulated albumen, as we have demonstrated by actual analysis.

We have tided babies over critical periods often with a few drops in its usual diet. We have given it to dipsomaniacs with or without non-alcoholic stimulants with superb results. The sole objection our patients have to it is its odor. Its taste is not disagreeable; it has the odor and appearance of blood. All objections are soon forgotten, however, in the results of its action upon the nutrition of the system, and the patient soon learns to like it, and often craves for it, drinking it from the bottle or a glass readily, like any beverage. It ought to be the food par-excellence for rapid appropriation in all conditions of exhaustion.

P. S.—Phosphates act well with the Liquid Food.

Maltine

WITH

COD LIVER OIL

A combination of the best Norwegian Cod Liver Oil with MALTINE, in which, by the vacuum process, rancidity is prevented and disagreeable odor and taste of the oil removed.

BASE A POWERFUL RECONSTRUCTIVE

CONTAINS NO INERT EMULSIFIER

Does not disturb Digestion nor offend the Palate

A complete list of the Maltine Preparations and their formulæ will be sent on application.

(Please mention this Journal.) THE MALTINE MANUFACTURING CO., New York, N. Y.

GOUDRON DE BLOUNT

PREPARED FROM THE GENUINE CAROLINA TAR.

DOSE.—One fluid drachm four or more times a day (as indicated), either full strength, diluted, or, in combination.

INDICATIONS.—Chronic and acute affections of the Air Passages, Coughs, Colds, Bronchitis, Asthma and Consumption.

WILLIAM MURRELL, M.D., F.R.C.P.,

Lecturer on Pharmacology and Therapeutics at the Westminster Hospital; Examiner in Materic Medica to the Royal College of Physicians of London; Fellow of the Medico-Chirurgical College of Philadelphia,

Says:—"I have used with success 'Goudron de Blount.' The results have been good, and the preparation is popular with patients."

Clinical Lecture.

TREPHINING FOR EPILEPSY.—FRACTURE OF THE BONES OF THE ANKLE. — SURGICAL TREATMENT OF PSOAS ABSCESS.

BY JOHN H. PACKARD, M. D.,

SURGEON TO THE PENNSYLVANIA HOSPITAL.

Gentlemen: The man who presents himself to our attention to-day has no especial family history bearing on his case; there is no history of nervous trouble in his family except that one uncle was an epileptic. Our patient was a healthy boy until he reached the age of fifteen, when, on returning from school one day, he was hit in the head with a brick. He became unconscious and was carried home in that condition. He retained apparent health for a year, until when sixteen; then while swimming he was suddenly seized with a queer feeling and became again unconscious. He then went six years without the recurrence of any similar symptoms. Then he had a number of repeated spells of unconsciousness, in one of which he fell and broke his arm. In 1858 he went to China, where he contracted gonorrhœa and in addition a chancre. He is a moderate drinker; his only other history is that of rheumatism. Now his attacks come on irregularly but with great frequency. He thinks that the heat of summer makes them appear at more frequent intervals; so that now he is in constant dread lest one may appear at any time. He is nervous and debilitated. When the attack comes on there is loss of memory first, then a convulsion appears in which there is total loss of consciousness; before coming to, he walks for squares without consciousness appearing; finally coming to his senses he finds himself far from the spot where the attack commenced. On going home, he finds that his muscles are excessively sore and weak as if they had been subjected to a severe pounding. On careful examination there has been found no disease in any of his organs; no albumin in his urine.

In a number of features this case differs from the history of a case of epilepsy as we ordinarily hear it. In most cases these convulsions and spells of unconsciousness come on without apparent cause. It is often a common experience to find children presented with the history of protracted spells of violent outbreaks of temper and terrific screaming spells; in these occasionally it has been noticed that they have fallen and examination discloses the fact that in the fall the tongue has been bitten. Again, ordinarily after an epileptic seizure, it is customary for the patient to fall into a heavy sleep, dull and stupid in its character, from which he awakes unrefreshed. It is not uncommon for an epileptic to run as the attack is coming on, although in many cases this may be limited to taking a few steps. I remember a patient that always ran for a stairway when his attacks came on; it is a remarkable fact that in these runnings he never pitched himself down-stairs to destruction. In some cases a preliminary cry is heard; it frequently occurs in a case of epilepsy that at first the cry is heard, but that as time goes on, that it gradually disappears, and finally ceases to occur altogether.

This man, from the nature of his malady, is incapacitated for work; he could not keep a position as clerk anywhere, for he is constantly exposed to these attacks and it would be most awkward indeed for himself and his employer to have them occurring in business hours, for they would seriously interfere with the quantity and quality of his work.

On careful consideration of the features

of the case I have determined to trephine him over the seat of his former injury, which is in the parietal region above the zygoma. At the point which he indicates as the place of injury from the brick, is a slight scar in the scalp and a depression in the skull. It is probable that his present malady comes from the blow, although the spells of unconsciousness did not appear in very close connection as regards time; still the connection between the cause and results is sufficiently reasonable for our purpose.

I have no idea as to the condition which we shall find within the skull. The internal table may be turned in, causing compression of brain substance. There may be simple adhesion between the inner surface of the bone and the dura and pia mater. There may be thickening of the brain substance at this point. We will be prepared for anything. Now as to the amount of risk run by the patient. The objection has been raised that in the necessary use of ether the epileptiform condition is liable to be produced; this need not influence us in any way; this condition in the epileptic under the circumstances is in no wise different from that induced in a normal subject. You will see that this epileptiform condition which usually appears in patients only after prolonged etherization, has appeared in this man almost immediately on his taking the first inhalations. It need not alarm us; we will treat it as in any other case, simply withdrawing the ether until the disappearance of the unpleasant symptoms. As he is now recovered from this condition we will make our first incision. In cutting the flap of skin covering the affected point, I do it in such a way as to allow the best drainage subsequently, as the patient's head reclines upon the pillow in bed. Hence the convexity of the curve is downwards. After I have taken out the plate of bone, I will use this platinum probe, which is bent at the end in such a way as to allow its insertion under the skull around the edges of the hole, to determine the condition of the inner surface of the cranial vault. If any spicula of bone is pressing down, this probe will detect it. Curious as it may seem, it is a fact that, although the operation of trephining has been known and practiced for a long time, it was not until the present century that the idea of cutting a semicircular incision in the scalp was published. Before this time it was the custom to remove the flap of skin entirely in performing the operation. Hay, in 1803, published the first suggestion of this idea; it may have been practiced before; if so, we have no record of it. Hay proposed a cruciform or semicircular flap.

The danger which we run from hemorrhage is as follows. In this region are found the terminal branches from the external carotid artery above the zygoma in the parietal region. These will not cause us much trouble; hemostats will control them if they chance to bleed too freely. On the inner table we have the branches of the middle meningeal artery; you have frequently noticed in your examinations of the inner table of the skull the grooves which branch here and there across its surface; in these grooves run the branches of this middle meningeal artery, on the outer surface of the dura mater. Sometimes these little arteries bleed furiously when cut. To stop this hemorrhage we will use if necessary a small pair of forceps, placing one blade within the skull and one without, compressing in this way the lumen of the artery. In applying the trephine we must not be too liberal in its use; the skull is rather thin at this point, hence we could easily go in too far. On removing this plate of bone I find that the probe passes freely around under the skull, showing that apparently there is no projection of bone and no adhesion as far as I can determine. The probe makes an uninterrupted passage around the entire opening. I have bitten away the edges of the opening to allow more extended opportunity for examination, all to no purpose. The dura mater bulges, as it should, into the opening; but it may require a puncture subsequently to relieve the pressure; the brain symptoms will reveal this necessity if it exists. At the temporo-parietal fissure the dura should be adherent. The temporal fossa is easily reached from this point; and if care and thought are not expended, it may be that fragments of normal bone will be removed.

I feel satisfied that the simple depression of the skull is sufficient to explain the occurrence of all the symptoms shown in this case. I am sorry for the sake of a brilliant demonstration, that I could not have removed a spicule of bone and have been able to say that it was the disturbing factor, but I have found enough for the present, and I see no reason for further interference, beyond biting away a little more of the edge of the hole. For a dressing we shall use iodoform gauze, placing it in contact with the dura mater, and not filling it in too close

for twenty-four hours, covering this with an antiseptic dressing. If no symptoms arise I may leave this dressing for forty-eight hours. There is a little troublesome hemorrhage from the edge of the wound; I will place a hair-lip pin around the vessel and throw a ligature around it. We also put in a catgut drain to assist in the free escape of liquids.

What good have we done? Often it is hard to see what the improvement of the symptoms is due to; here a depression has been removed. This depression may cause congestion of the membranes of the brain, repeated at frequent intervals and slowly growing more severe and prolonged.

Fracture of Ankle.

The next man has trouble at the other end of the body. He presents a history which is not uncommon. Eight days ago he was admitted to the hospital suffering from the effects of a fall from the second story of a building. He alighted on his heels; the skin over one ankle was broken and there was free bleeding. Several bones—it is difficult to say exactly which ones—were fractured. The same condition existed in the other foot, except that that was no solution of the continuity of the skin. The question immediately arises on seeing a case of this sort, of what should be done. It is not best, I believe, to attempt to make accurate apposition of the fractured bones; this would require dissection of the parts and would do more harm than good. It is better to make moderate extension and reduce all apparent deformity in the ankles. There will be undoubtedly some subsequent stiffening. In this case we have simply applied lead-water and laudanum dressing, to subdue the inflammation; after the swelling has subsided sufficiently, readjustment of the displacement will be made as carefully as possible. I had a case some time ago which reverts to my mind. A gentleman leaped from the window during the excitement of a hotel fire, landing on his feet. There was such severe contusion that I etherized the man, but found no fracture. Eventually he recovered but with inability to bend the foot in and out. He was an amateur organist of considerable ability; unfortunately he found that this was the exact movements required for the pedals. It was a great disappointment but he will gradually recover the movement in the course of time.

Psoas Abscess.

The next case is one of psoas abscess; the man who lies before you has one such abscess; but a sudden rise of temperature and the appearance of symptoms of severe sickness was followed by the discovery of a swelling on the other side, which on opening under ether revealed the existence of pus. I am going to present the case to my colleagues and if they assent I will follow the route of these abscesses back to the carious vertebræ which they represent and if possible will remove all the carious material. I have seen these cases, fifty at least in the past twenty-eight years, present themselves with this man's history and all go on to the same termination. At other points of the body we remove carious bone; we take it out of the fibula or femur; if it can be taken from the vertebræ it would be most excellent. The operation is not so radical and difficult or serious to life as you would imagine at first thought. The route has been made for us; all that we would have to do would be to follow it.

COMMUNICATIONS.

ERGOT IN TYPHOID FEVER.[1]

BY T. B. HILL, M. D.,
RUFF'S CREEK, PA.

Ergot stimulates the unstriped or involuntary muscular fibre to contraction wherever found. Such fibre is found in the alimentary canal from the middle of the œsophagus to the internal sphincter ani, in the posterior segment of the trachea and the bronchial tubes to their finest ramifications, in the heart, in the middle coat of the arteries, veins and lymphatic vessels and in other situations.

In the treatment of typhoid fever, prior to the advent of the so-called specific methods, the proper thing to do, seemed to be to mitigate the more prominent and unpleasant symptoms, and to guard the avenues of danger. Moreover, however meritorious in themselves, the newer ideas have not usurped and cannot usurp the place of the old. We are not cognizant of the disease apart from its symptoms—headache, fever, diarrhœa,

[1] Read before the Tri-County Medical Society at Washington, Pa., October 15, 1890.

depression, abdominal pains, tympanites and intestinal hemorrhage. Then we have the specific lesions—enlargement of the mesenteric glands, with deposit in the glands of Peyer, which usually advance to ulceration. One of the earliest and most persistent symptoms is feebleness. Not only is the gait staggering and uncertain, but there is also relaxation and want of tone in the muscles of the entire economy. A marked example is the softness of the pulse and the feebleness of the first sound of the heart. Relaxation of the smaller blood-vessels is common, as shown by the numerous mucous congestions. Epistaxis is a common, and diarrhœa an almost universal early symptom.

From a careful study of the pharmacology of ergot, I was led some years ago to believe that in it we have a drug capable of meeting more of the indications presented in typhoid fever than can be met by any other single drug or combination of drugs at our command. At the same time it is extremely simple and entirely harmless.

The symptom which earliest and most loudly calls for treatment is headache. I am aware that there has been some difference of opinion as to the pathological condition on which the headache depends, but the preponderance of evidence is in favor of congestion. The value of ergot in congestion of the central nervous system is well established, hence its indication here.

The condition of the circulation is another circumstance which, though not so self-asserting as the headache, is of far greater importance and ought to receive much earlier attention than is generally accorded to it.

Prof. Pepper in a clinical lecture says: "Among the indications to be considered in the prognosis, I have mentioned the heart and the pulse. This is exceedingly important. I think that the study of the sounds of the heart—of the strength of the muscular or first sound of the heart, the strength of the impulse, the way in which the artery fills at the wrist, how it resists pressure, the quality of the beat, the frequency of it and its regularity—is of the first importance in the prognosis of typhoid fever; and as a guide to treatment, especially in regard to the important question as to the administration of stimulants. In a case in which the pulse-rate is from 120 to 140 per minute, very compressible so that it collapses under the slightest pressure, with an exceedingly weak first sound, so that it assumes an almost valvular character, stimulants may be given freely." I have given this quotation to emphasize the importance of giving earlier attention to the condition of the circulation. If it is of the *first importance*, as Prof. Pepper says, why should we withhold the hand until we are confronted by the critical condition he describes? Simply, I presume, because no one is willing at an earlier period to resort to stimulants (by which is meant some of the forms of alcohol), because they are not capable of accomplishing the desired good, and because they may accomplish undesired evil. They cannot accomplish the desired good because their force is directed to the nervous system, which at this early period is not at fault. They may accomplish undesired evil, because the stage of depression which follows overstimulation may overtake the patient at a time when his vital powers are not able to withstand it. In ergot, on the other hand, we have an agent which, by directing its energies to the weakened muscular structures, causes the heart to contract with more firmness and regularity, while to the arteries is restored that resiliency which enables them to carry forward the circulating fluid with healthful vigor; and a condition of self-confidence is imparted to the entire circulation.

Diarrhœa is a symptom which is present in a large part of all cases of typhoid fever, and usually at one stage or another calls for some kind of treatment. The use of ergot in diarrhœa and dysentery is not a new thing. The indication is as well marked here as in any other form of diarrhœa.

Intestinal hemorrhage is a symptom which I believe is always dreaded. Almost everybody prescribes ergot when hemorrhage has actually taken place. I hold that it would be better practice to fortify, not only against intestinal hemorrhage, but also against all forms of hemorrhage by an early resort to the use of ergot.

With the causation of typhoid fever the present discussion has nothing to do. But whether it be due to a specific microbe or not, the special lesion is hyperemia of the intestinal mucous membrane with foci of inflammation in the glands of Peyer. Here the indication is to remove the hyperemia and to starve out the inflammation. If there is a drug in the materia medica available for this purpose, it is ergot.

Tympanites is often a serious trouble, and

sometimes goes so far as to constitute an important element in the prognosis. By its upward pressure it causes marked interference with respiration, and adds greatly to any pulmonary complication. In the same way it hinders the free action of the heart. It is caused by fermentation of the ingesta, and is made possible only by the relaxed state of the muscular layer of the intestinal wall. Stimulate these muscles to maintain the caliber of the intestine at its normal dimensions, and tympanites can no more occur in the typhoid patient than it can in an individual enjoying perfect health. This looks like a strong statement; but it is not inadvertently made.

Perforation may be very appropriately spoken of as the "king of terrors" in typhoid fever. I do not say that it can be entirely prevented. I know there are cases, apparently the mildest, not seeming to call for any medication whatever, which, without any premonition of danger, suddenly develop the intense abdominal pain, the chill, the collapse, that only too unmistakably tell the sad story of a perforation. But I do say that when we permit the inflammation in the intestinal glands to run its course unimpeded to final ulceration, and when we permit the intestine to be distended to its fullest extent—the ulcers stretched to many times their original size, the thickness of the wall at their bottoms diminished to the most extreme tenuity, while the volume of pent-up gases, continually reinforced by the putrefactive processes, momentarily threatens to burst through the fragile structure and sound the knell of the unfortunate victim—then, I say, we have done what we could to render the untoward event not only possible but probable. If, however, we have, as already intimated, made use of means to remove the hyperemia and to starve out the inflammation—if we have limited the size of the ulcers, while we have preserved the normal dimensions of the gut and the tonicity of its walls, compelling the generated gases to move on instead of accumulating in such proportions as to be an ever-present menace to the life of the patient, we will have reduced the danger of perforation to the minimum. Again the indication points to ergot.

Now, having shown that ergot is indicated for headache, for the circulation, for diarrhœa, for the intestinal lesions, for tympanitis, for hemorrhage, and as a safeguard against the almost certainly fatal perforation, it remains to ask: Is ergot capable of fulfilling these indications? My experience is yet so limited—and that is my only source of information—that I say it with timidity, but I feel able to answer: It is. The apparent results have been so uniformly and almost universally gratifying, that I am glad to believe this is not a mere coincidence. My cases may not have been the worst; but I have not lacked bad cases. In one instance the thermometer marked 106° for six consecutive days. Not only has the ergot had a salutary effect on the headache, but it has seemed to ward off delirium and other nervous manifestations which are apt to appear later in the attack. In the case already referred to, in which the temperature was 106° for six days, there were absolutely no nervous symptoms, and no other bad symptoms but the temperature.

In order to anticipate adverse criticism, I may say that I am not in sympathy with the antipyretic treatment, as a prominent factor in the management of typhoid fever.

Under the ergot treatment I have never seen more than the mildest delirium. I have seen very little somnolence, and no coma-vigil. I do not remember having prescribed anything else for diarrhœa, but have frequently prescribed for the opposite condition. I have never seen a case of intestinal hemorrhage. I have not seen tympanites beyond the slightest degree of fulness. I have seen only one case in which, as I now think, it was necessary to resort to alcoholic stimulation to sustain the flagging energies of the heart. This was the case of a woman in whom the menses came on in the second week of the disease and lasted one week; during which the ergot was suspended, and after which it seemed to have lost its usefulness. In this case there was decided failure of the heart which demanded the use of alcohol. I have seen no case of perforation. It goes without saying, I have seen no fatal case.

It would seem superfluous to enter into any detail of the manner of using ergot, so simple is it, yet this brief resumé might appear incomplete without some reference to that part of the subject. I have used only the fluid extract, in doses ranging from twenty to thirty minims every four, six or eight hours, as the case might require. Since beginning the use of ergot, all of my cases—about thirty—have been treated in this way from the commencement until convalescence was established, except the one case mentioned.

There is of course nothing specific in this treatment; nor is it intended to supplant specific medication, in which I believe, and which I practice in combination with ergot. All that is claimed for it, is that it is the simplest, safest, most rational and most efficient symptomatic treatment conceivable. As such I respectfully submit it to the consideration of the members of this society, with the hope that some, at least, may think well enough of it to give it a trial.

AN ANOMALOUS CASE OF MEASLES.

BY J. C. WILSON, M. D.

The following case illustrates two points of importance in regard to the acute infectious diseases:

1. Variation from the ordinary type; 2. The difficulty of diagnosis in atypical cases.

Case.—Atypical measles; sudden onset; absence of coryza; erythematous sore throat; scarlatiniform eruption.

G. L. J., sixteen years old, a school boy, had suffered from rötheln some years ago. He had never had measles or scarlet fever, and was peculiarly liable to attacks of sore throat. He had mild enteric fever in September, 1890; made a good recovery, and was in his usual health.

November 27, upon rising, he felt chilly. The chilliness and shivering continued throughout the day. Towards evening his throat became sore. There was no sneezing, no coryza, and no cough.

November 28. The boy was feverish and indisposed, and had what he describes as a severe attack of indigestion, but without vomiting. He had no appetite, a good deal of pain on swallowing, and pains in back and joints. His evening temperature was 102° F.

November 29. He had a brilliant erythematous inflammation of the soft palate, uvula, half arches and tonsils. His tongue was thickly coated with yellowish white fur, and his bowels were constipated. His urine was non-albuminous. He complained of throbbing headache and backache; the pains in the joints had disappeared. His face was slightly flushed but free from eruption; his eyes were suffused, but not intolerant of light. There was still no sneezing; no cough; no râles. Upon examination, the neck, thorax and sides of the abdomen were seen to be covered with a diffuse erythematous exanthem, resembling that of scarlet fever. The back and extremities were free from rash. The pulse was 112; the temperature 100° F. The evening temperature was 102.4° F. The boy was now given hydrag. chlorid. mitis, gr. v; pulv. morph. comp. (Tully's powder) gr. ii, every two hours.

November 30. The throat was less painful, but still deeply red; there was no eruption over the mucous membrane covering the hard palate. The diffuse scarlatiniform eruption had extended over the face, trunk, upper extremities and lower extremities as far as the knees. Upon the legs and arms it was most conspicuous upon the extensor surfaces, but it also covered the flexor surfaces. When viewed at a short distance it preserved its uniform appearance. Upon closer examination it seemed to be punctiform, and the hair follicles were seen to be especially swollen and congested. The texture of the patient's skin was rather coarse. There was also on this day some irritative cough; but upon auscultation no râles were discovered. The morning temperature was 102.4° F.; the evening temperature was 103.4° F. The use of calomel was followed by two large movements of the bowels.

The patient was now given

℞ Chloral. hydrat., ... gr. iii
Syr. lactucarii (Aubergier's) . . . . ♏ xv
Aquæ . . . . . ♏ xlv

every two hours.

December 1. The throat was much better, and the cough no longer troublesome. Upon the face, chest and extensor surface of the extremities, the rash preserved its former appearance; on the flexor surface of the fore-arms, the diffuse rash had disappeared, leaving the dull, red, occasionally discreet, flat, papular eruption of measles, with characteristic curvilinear and crescentic arrangement. The exanthem of measles showed itself on this day upon the legs below the knee. The morning and evening temperature was 101.4° F.

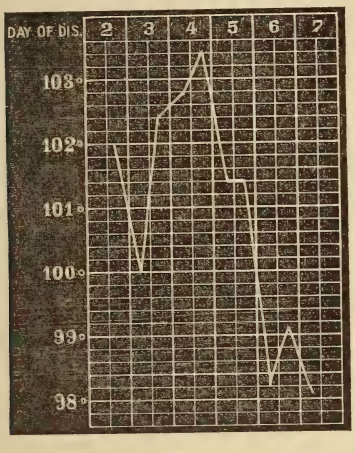
December 2. The morning temperature was normal; the throat was well; the exanthem was everywhere rapidly fading.

December 6. Convalescence was fully established; and there was a fine, scaly desquamation of face and neck; the temperature was normal, the urine not albuminous.

December 12. A brother of the patient,

eleven years old, who had been sent to the house of a relative, was brought to me on account of a troublesome irritative cough and sneezing, which had lasted two days. The following day he developed the eruption of measles.

This case, trivial as it appears when thus set forth, is not without practical interest. During the first three days a correct diagnosis was practically impossible. It was only upon the fourth day, when the fading erythema brought into relief the exanthem of



measles on the flexor surfaces of the forearm, and when the same eruption appeared upon the legs below the knees, that a doubt arose. The subsequent history of the case renders the diagnosis of measles alone tenable. The abrupt onset, with shivering and erythematous sore throat; the site of the appearances of the rash and the mode of its distribution; the absence of coryza; the insignificant catarrhal symptoms; and the temperature range, taken altogether, constitute in this case a wide variation from measles in its ordinary form.

The practical bearing of such a departure from type in any of the exanthematous diseases especially occurring in private practice requires no comment.

Women Pharmacists. — It is said that there are now four women students of pharmacy in Philadelphia, and already, before they are near their graduation, three positions are waiting for them. Rather different this from the mob of poor sewers ever besieging the gates of that kind of employment—gates at which only one may be admitted for ten left outside.

WHEN IS TOTAL HYSTERECTOMY INDICATED? A PLEA FOR CONSERVATISM.[1]

BY F. SHIMONEK, M. D.,

MILWAUKEE, WIS.

In looking over the literature of hysterectomy for carcinoma of the cervix, my mind became imbued with the idea that the very wide differences in the views of authors regarding the propriety of total or partial extirpation, depended upon certain positive pathological elements and required extra vigilance in order to arrive at a correct opinion in regard to this important subject. I therefore desire to read this short paper regarding some points as means of differentiating the malignant neoplastic proliferations affecting the cervix uteri, as bearing on the selection of the proper operation. The kind of histological elements found in the new growth, to my mind, should influence the selection of the proper surgical procedure.

Since I have arrived at this conclusion, I saw in the *Medical Record*, September 6, 1890, an opinion expressed by Dr. John Williams, that "in cases of cancer of the cervix and of the portio vaginalis the propriety of operation depends upon the pathological variety of the neoplasm, etc." Therefore, I claim that no man has the right to perform total hysterectomy without having satisfied himself beyond all doubt that he is dealing with a neoplasm whose great tendency is early to infiltrate the body of the uterus. Of course, this has reference to the early stage, for in advanced cancerous degeneration, whether it be cancroid or carcinoma, only one thing is proper, if any, and that is total extirpation. There are chiefly the two varieties—squamous-celled carcinoma or epithelioma, and the spheroidal-celled carcinoma, or the glandular or true cancer, which frequently affects the cervix. The epithelioma is the most frequent, and ordinarily it is primarily a superficial lesion, which, as the growth advances, gradually involves, as a rule, the surrounding tissue and only towards the end in some cases, infiltrates the body of the uterus, though only very exceptionally,

[1] Read before the Milwaukee Clinical Society, October, 1890.

as the great tendency is to destroy more and more of the infiltrated tissue rather than the establishment of numerous and remote foci of infection.

It is an undoubted fact that the epithelioma is not so malignant and is better amenable to the knife than the glandular cancer. Now, I think that the contradictory opinions, regarding the selection of the most proper procedure, completely ignore this undoubted and important factor in the diagnosis early in the invasion of the neoplasm. Such has been the success of some of the operators who prefer the partial operation, notably Baker and Byrne, that they report the average length of life, I think, to be about eight years. Byrne reports the cases of two women, who, after the operation, conceived and not only carried the children to full term, but gave birth to them without any special difficulty. If the teachings of some celebrated men had been followed, those women would have been consigned to barrenness. We must not forget, that, "In all gynecological operations the ultimate aim must be the preservation of the sexual activity." Therefore, it is the duty of every one who does work of this kind to investigate the exact pathological nature of the infiltration early, and not simply to make a diagnosis of cancer, and there let it rest.

There is no doubt but that the partial operation is comparatively simple, whereas complete hysterectomy is liable to be a formidable procedure, and the difference in the fatality of the operations is greatly in favor of the partial one. The glandular carcinoma commences deeper in the tissue and has a greater disposition to infiltrate the corpus uteri early; the greater malignancy of this variety is too well known to require an extensive argument in its support, and its tendency to recur is consequently also very much greater. Therefore, I contend that, it is of prime importance to make a most thorough histological research as early as possible in the invasion of the new formation, and for that purpose it is not generally sufficient to secure, merely, some scrapings or excise small pieces, but one must remove large wedge-shaped pieces or the whole intra-vaginal portion, if necessary, in order to make a comprehensive investigation; because one cannot judge of the condition of the whole by examining a small fragment thereof.

My argument is, then, if careful microscopic examination shows a squamous-celled growth confined to the cervix uteri, one should perform supra-vaginal amputation; but if there be present a spheroidal-celled arrangement—be the neoplasm of ever so small dimensions—the probability is that there are widely scattered foci throughout the uterine parenchyma; and then total extirpation is most certainly the proper method. My own experience in this matter is very limited, but from a careful perusal of this subject I determined to make it the subject of these few remarks.

It may be appropriate in this connection to present the report of a case of malignant uterine neoplasm, with microscopic illustrations, which in a measure bears on the necessity for careful and thorough investigation for diagnostic and prognostic purposes. The case very positively proves that it is not sufficient to examine only a few scrapings. The specimens which I shall take the pleasure to exhibit to you, were made from a uterus which was wholly extirpated for an extensive malignant degeneration of the cervix uteri, supposed to be confined to that locality; but the microscope has since shown cells in their embryonic state, the so-called indifferent tissue or the pre-cancerous state, extensively distributed throughout the whole organ; and I have no doubt but that there were cells in the lymphatics and lymphatic glands in the pelvis. The only symptom of which the patient complained, at the time of presenting herself, was hemorrahage during coitus, which led me to examine the patient, and to discover the real state of affairs.

The first slide, which I show, was taken from a squamous-celled cancer of the cervix, and it very beautifully shows the typical cells and cell-nests. The next slide, which shows a specimen from this case here reported, was made from the cervix uteri in the immediate vicinity of the internal os, and it positively demonstrates the pathological difference between this and the preceding one. This section shows the mature spheroidal-celled carcinoma. You will notice that the cells are small, as compared with the squamous cells, and round, containing a nucleus and granular matter, also quite a development of inter-cellular fibrous tissue. This alveolar arrangement inclosing masses of spheroidal cells is characteristic of true cancer and the consistency depends upon the amount of the fibrous framework. The next section, which was made also from

the cervix, but nearer the external os, shows a different construction, and it would lead a man astray if he were to prepare only one slide. It is more like small, round-celled sarcoma, and in fact it is so much like it, that from one section it would be impossible to call it anything else; but it is the pre-cancerous or embryonic tissue, or, as Maier's researches seem to show, the transformation of a sarcoma into cancer. Klebs denominates these (somewhat rare) mixtures, *carcino-sarcomata.*

The next slide was prepared from a polypus-like growth, which was situated near the internal os in the cavum uteri, which, you will perceive, shows the same sarcomatous appearance. The last sections were taken from remote parts of the body of the uterus and mucous membrane, and, in addition to the muscular tissue, show on quite close inspection similar small-round cells, which I mistook, at my first examination, for a transverse section of some muscular fibers, but since they are scattered irregularly among bundles of uterine muscular fibers, and bear a very close resemblance to the primitive cells, I am forced to conclude that they are all neoplastic cells.

Judging from the maturity of the glandular cells and inter-cellular fibrous tissue found in the deep part of the cervix, from the great rarity of cervical sarcoma, from the wide but sparse diffusion of the embryonic elements, I conclude that this was a case of true cancer with extensive infiltration.

The operation was quite difficult on account of the great size of the cervix. The patient succumbed to shock in about twelve hours. She nearly perished on the table, but rallied again, then failed and died.

What I have said has been with the design of suggesting and urging further and more accurate microscopic work and of pointing out the distinctive features of these epithelial new formations and their relations to the malignancy and infiltrating tendencies, as bearing on the selection of the proper surgical measures.

—Iodine, free from chlorine, is obtained (*Pharm. Centralh.*) by placing commercial iodine in a beaker glass and covering with a concentrated solution of potassium iodide. Place over the vessel a plate of glass, and apply heat until the iodine is melted. After cooling, collect the iodine crystals on a filter, and wash with distilled water.

CASE OF PERITONITIS.[1]

BY R. J. TRIPPE, M. D.,
CHATTANOOGA, TENN.

On November 4, 1889, Ed. Stokes, 32 years old, a strong heavy-set negro, came to my office about 8 A. M., suffering excruciating pain in the abdomen, having received a blow with a crow-bar across this part of his body. Perspiration stood in large beads all over him. His radial pulse was imperceptible. He was not able to tell me anything about how he had been hurt. I administered a hypodermic of morphine, half a grain, and of atropine one-seventy-fifth of a grain, and gave him stimulants freely. In about an hour he felt very much better, and was placed in a hack and sent to his room, a distance of about eight blocks. I saw him later in the day, when he informed me he felt well enough to get up; but when an attempt was made, he discovered he was too weak. His appetite was good, and he was not thirsty. I told him to remain in bed until I saw him.

The next day, at 9 A. M., I saw him again. He now said he was feeling first-rate, and had taken food regularly and relished it. His tongue was heavily coated with brown, and was thick, broad and flabby. His breath was very offensive; he had no pain in the bowels, had passed urine without pain; and had no tympanites or tenderness, even on very deep pressure. I ordered calomel and soda āā gr. x, to be followed with sulphate of magnesia in a few hours.

On November 6, the third day, at about 3 P. M., without any warning, stercoraceous vomiting set in; but I did not see the man until 9 o'clock. His temperature was then 96°, his pulse 130, and he was wet all over with cold perspiration. I filled his stomach and bowels with hot water, with a view to overcoming the obstruction if possible. The water injected into the bowels came away as clear as it went in, but that in the stomach was accompanied by fecal matter. At 12 o'clock, as my patient got no better, I determined to wait no longer, and at 2 P. M. I opened the belly, and to my utter surprise found the entire cavity full of the most offensive pus I ever saw. (I may mention that even then there was not the slightest pain or tenderness of the bowels). The intes-

[1] Read before the Tri-State Medical Association, October 16, 1890.

tines were all adherent, and perforated in several places.

I realized at once that the case was a hopeless one, but proceeded with the operation as though I expected a good result. The perforations were closed with catgut; the adhesions were broken up and the guts separated; and the cavity was washed out with warm sublimate (1 to 20,000) until it returned perfectly clear. A drainage-tube was put in, and the wound was closed and dressed in the usual way. The patient was then put to bed, and packed with hot bottles. Reaction was prompt, and the temperature in three hours was normal. The man suffered no pain on the night after the operation, and had no nausea or vomiting.

On November 7, the fourth day, I saw him at 9 A. M. He then said he had had a good night, was hungry, and felt so very well that he declared he was going to get well. His bowels had begun to move, and the discharge had the appearance of bloody water mixed with pus. His diet consisted of milk and whiskey at regular intervals. His temperature was normal, his pulse 90.

On November 8, the fifth day, at 9 A. M., he was resting well, and said he had had a good night. He was still hungry. His temperature was normal, his pulse 78, his bowels still active. At 6 P. M. he was resting well, with a temperature of 99°, and a pulse of 90.

On November 9, the sixth day, at 10 A. M., his temperature was 98½°, his pulse 80. He said he thought he would be up in a few days. His bowels were still acting, and the movements of better character. I ordered the same diet to be continued.

About an hour later I was passing, and on inquiry I learned that my patient had suddenly grown worse. His temperature was 95°, his pulse 120, and at about 11 o'clock he died.

VALUE OF THE KOCH REAGENT FOR TUBERCULOSIS.

BY SAMUEL G. DIXON, M. D.,
BACTERIOLOGIST, ACADEMY OF NATURAL SCIENCES, PHILADELPHIA.

In considering at present the therapeutic value of the Koch remedy for human tuberculosis, we must weigh its power for good against its power for evil.

In lupus affections the reagent certainly produces an active inflammation, which causes death of the recognizable tuberculosis tissue. During treatment of lupus, a nodular infiltration takes place. The œdema in many cases is exaggerated. As the fever subsides, prostration is often experienced, the nodules gradually become covered with a crust, under which can be detected a healthy looking granulation. When these crusts fall off, young, red cicatrices are to be seen. The cases soon present the appearance of a perfect cure. This condition, however, does not always remain. In after weeks the characteristic inflammation of lupus again appears, and the process goes on as before.

Query. Does the reagent destroy all tuberculous tissue or does it only destroy that which we recognize? Time must answer.

Owing to the suppuration set up by the action of the Koch remedy in the vascular tissues, immediately surrounding the tubercles, the remedy is positively contra-indicated in tubercular meningitis.

With all internal tuberculous affections there is more or less danger of disseminating the bacilli. If the remedy attacked the bacillus as it does recognizable tuberculous tissue there would not be that danger.

In surgical tuberculosis, where there is not a marked predisposition of the tissues, we have much reason to look for success. Such cases more closely resemble the experimental animal cases than those of other characters. In these we should have all the advantages of the remedy and fewer of the disadvantages than in most others. Here the reagent may produce a degree of active tubercular inflammation sufficient to cause the death of the tubercular tissue, yet not affect tissues which are not predisposed to tuberculosis.

Time may show that the Koch remedy does not injuriously affect any tissue other than that which we can recognize as tuberculous. However, at present, no one can say that the new manifestations of tubercular lesions only arise in tissues previously tuberculous. The dissemination of the bacilli by being taken up into the circulation may produce the tuberculous process in parts that would under no other circumstances have taken on the tubercular process.

I must call attention to the fact that the remedy causes an acute inflammation in all live tuberculous tissues. All the vascular tissue surrounding tubercles, when under the influence of the remedy, is loaded with small round cells. The wandering cells are

even found working themselves into the giant cells. Hyperemia is produced. Each tubercle becomes the centre of an inflammation in the lung. Therefore in proportion to the lesion, the alveoli in the periphery of the tubercle are rendered incapable of performing their duties. In very extensive dissemination of tuberculosis, the enormous decrease in the functionable lung parenchyma may prove disastrous to life. This would, therefore, lead us to believe that the remedy is contra-indicated in widely disseminated invasions on lung tissue.

In laryngeal tuberculosis, we must remember, should the area of disease be very extensive, that this same infiltration of small round cells and hyperemia with œdemia may also endanger life.

Experience has taught us that there is lurking danger that cannot be foreseen. This arises from the fact that tissues may be tuberculous to a degree susceptible to the action of the Koch remedy, when not otherwise recognizable, or again it is, as I have already said, made tuberculous by the process set up by the remedy. This is to be explained, possibly, by dissemination of the live bacilli. Just here I venture to say I do not approve the method of performing massage with tuberculous joints after treatment with the reagent.

If there is any known substance that will stimulate white blood corpuscles to break up foreign matter in the blood of the living animal, it should be administered during the Koch treatment. Iodide of potassium may assist indirectly in disposing of the bacilli during and after treatment.

There is one question that time alone will answer, to wit: Is the tissue immediately adjacent to the tuberculous tissue necrosed by the inflammatory process set up by the Koch remedy sufficiently tuberculous to slowly develop into recognizable tuberculosis, or is it rendered more susceptible to the action of the bacillus?

In referring to the menstruum sold by Dr. Libbertz as the Koch remedy or liquid, it is, I am inclined to believe, a menstruum made up of glycerine, gelatine and a metabolic product of the tubercle bacillus. This latter represents about one thousandth part of the mixture. Probably the menstruum contains a gold salt.

If the liquid contains that produced by the tubercle bacillus, we cannot be surprised at its special action on tuberculous tissue alone, yet it would not be very surprising if it should react on leprosy. The bacillus of leprosy has characteristics in many respects corresponding to the tubercle bacillus.

If the action of the tubercle bacillus on the animal tissue is wrought by a process of digestion, we might seek to produce its digestive ferment by growing it on an artificial medium, inoculating and introducing it into the animal economy, already the prey of the tubercle bacillus. In this tissue the bacillus would be found secreting virus enough to inflame and break up the tissue to a degree suited for its absorption and existence. The artificially added product or digestive ferment would break up the chemical relationship of the constituents of the tissues to a degree beyond that suited for the consumption by the bacillus. The inflammation produced would possibly be so acute and severe as to kill all recognizable tuberculous tissue.

When in Berlin, Prof. Dr. Koch personally expressed to me his confidence in the remedy to successfully combat lupus and laryngeal tuberculosis.

I am inclined to the belief that the remedy should be very cautiously administered to man and that laboratory work should be energetically carried on.

Foreign Correspondence.

BERLIN LETTER.

The Berlin Aquarium.—A Chicago Doctor's Adventure. — Luxation of Crico-thyroid Joint.—"Ether-Fritze."—Pennyroyal as a Poison.—Antisepsis for Chiropodists.—Death from Bromide of Ethyl.

Visiting the Berlin Aquarium the other day, I was fortunate enough to witness the representation of an interesting biological scene before a distinguished invited company, among whom were the Minister of Public Worship (Cultus Minister) and several University Professors. Dr. Hermes showed the reviving of African salamander-fish after an eight months' sleep. The fish were encapsuled in pieces of clay weighing about twenty pounds. These were partly placed in water, partly broken, the encapsuled fish freed from the surrounding mucus and also placed in water. Almost directly the fish showed signs of life, and after the expiration of a few minutes swam

freely to and fro. In case of the encapsuled fish the reviving process occupied a longer time. The trotopterus, after having lived as an amphibious animal, showed up invariably as a lively fish. The Berlin Aquarium—especially since the government has erected a station at Rovigno, Italy—contains the most interesting collection of submarine life in existence, and is one of the great points of attraction to visitors.

Speaking of visitors to Berlin, I cannot refrain from telling you about an exceedingly interesting adventure happening to a Chicago physician during the Congress. The Illinois man passed over the Linden late at night reflecting over the glory in store for his native city. Suddenly a suspicious-looking individual hustled by, closely touching the doctor. The latter, with the ingenuity of the Western man, felt for his watch, and missing it unhesitatingly began the pursuit of the robber. The suspicious individual fled through the Brandenburg Gate into the Thiergarten, the American doctor in close pursuit, loudly crying "put up that watch!" Near the Victory Column the robber was caught by the doctor, and compelled to deliver the watch, after which he was released. The Chicago man returned to his hotel, proud of himself and of his native city and country. But, lo! on the table he beheld his watch, which he had forgotten when leaving the hotel. Next morning all the papers published the story of a robbery in the Thiergarten: a French doctor, they said, had been pursued by a burly, powerful robber, attacked and robbed of his valuable watch.

Professor Braun, of the Kœnigsberg University, published the first case of habitual luxation of the crico-thyroid articulation ever described, and—what adds to the interest of the matter—observed on his own person. By a singular coincidence the Professor had the opportunity to observe two other cases of the same character. On himself, the luxation appears on deep inspiration and during gaping. It is not simultaneous on both sides, but occurs either on the left or the right side. At times the luxation occurs daily, again months may pass without it. A sensation of oppression and great anxiety is invariably connected with the phenomenon. Reduction can be obtained in a very simple manner by mere manual pressure or the act of swallowing.

A few days ago I renewed a very strange acquaintance made many years ago. Passing Stralauer Strasse in the forenoon, I saw an oddly-dressed man of about thirty-five standing before the window of an art gallery and making incessant and profound bows before the pictures of the Imperial Majesties. Approaching the queer patriot, I noted at once a penetrating odor of ether. And seeing the man pouring some of the contents of a bottle into his handkerchief with the experience of a skilled anæsthetiziser, I understood the situation. The man in front of me was "Ether-Fritze," the well-known victim of etheromania. The deplorable individual belonged to a rich and highly-cultured Berlin family, and had studied chemistry and medicine. In a chemical laboratory I had first met him. Later on he was anæsthetized in a surgical clinic, where he acquired the unfortunate habit. At present he eats almost nothing, the only desire he has being for ether, the stimulation of which keeps him up. He consumes about a pint a day, and it is thought that he would die if he should dispense with the use of the drug. I was told that there is another individual with the same habit in Berlin, a former Demonstrator of Dentistry.

Drs. Falk and Langgard, assistants of Prof. Liebreich, have recently instituted at the Pharmacological Institute a series of researches to determine whether pennyroyal is a veritable emmenagogue, and how its action is brought about. The drug, as everybody knows, being very frequently used by women without medical advice, the question whether pennyroyal is a harmless remedy is not void of interest. Haller, Govan and Marshall regard the drug as an abortifacient, while Taylor holds an opposite view, and in addition believes the drug to be quite harmless. From two to three grams of pennyroyal, given to rabbits internally or subcutaneously, produce no signs of intoxication save a conspicuous loss of balancing power. The animals stagger from one side to another. A dose of three grams suffices to paralyze the animal. Exceptionally lethal effects have been noted after comparatively small doses. Autopsies reveal invariably parenchymatous degenerations in the principal organs. The liver appears chiefly affected, showing in case of protracted exhibition of the drug, an enormous swelling; the parenchyma is brittle, the peripheral zone of acini presents yellowish foci, often as large as a bean. The heart and kidneys show yellow dots and lines; the urine contains casts and albumin. It is clear then

that pennyroyal, like phosphorus, produces fatty degenerations of the organs. Regarding the action of the drug upon the heart, the experimenters noted a slight increase of blood-pressure, resulting from a slowing of the heart's action, due to a stimulation of the pneumogastric nerve. Hence it must be said that the emmenagogue action of the drug is due solely to its deleterious effects upon the various organs, and that women ought to be cautioned against taking the drug without the physician's order. A number of accidents—collapse, disease of the liver, etc.—from the use of the drug have been observed by Dr. Marshall and others.

A recent order of the police demands all "corn-doctors" to employ perfect antisepsis in their surgical manipulations. The fact that a number of accidents have occurred here of late in the office of a chiropodist has given rise to this desirable ukase. Would it not be indicated to extend the order also to the tonsorial artists?

Recently Dr. Edel, a Berlin dentist, caused the death of his apprentice by the unwarranted administration of bromide of ethyl. The enterprising dentist, not contented with the effects of chloroform given for the extraction of a molar, resorted in addition to bromide of ethyl and promptly killed the boy. Dr. L. Lewin, Docent of Pharmacology at the Berlin University, ascribes the accident exclusively to the combination of the two anæsthetics, which he regards as an inexcusable blunder. Others again claim that the drug was impure, and that the dentist is not to be blamed for the accident. It is certain that with the exclusive use of bromide of ethyl, prepared by Merck, no accidents have been reported even by dentists who, like Dr. Gilles, of Cologne, have administered the anæsthetic in nearly a thousand cases. At the University Dental Clinics bromide of ethyl is never used, as Prof. Busch has had some very unpleasant experience with it. With proper individualization, however—exclusion of nervous and otherwise organically affected persons—bromide of ethyl appears a perfectly safe and very eligible anæsthetic for dental and minor surgery.

—To diminish the danger to life and property from electric wires, the Common Council of Boston, Mass., have passed an ordinance to appoint an inspector of wires, who shall have charge of all wires in the city.

PERISCOPE.

Relative Value of Various Anæsthetics.

In a discussion on anæsthetics before the Medico-Chirurgical Society of Glasgow, Dr. T. Brown Henderson read an interesting paper, which is published in the *Glasgow Medical Journal*, November, 1890, in which he said that next to ether and chloroform nitrous oxide gas appears to be the most useful anæsthetic agent. For short operations, requiring only a brief narcosis, it is admirably adapted, as it is rapid in its operation, and recovery from its effects is equally speedy, and it can be employed anywhere. It is gaining the confidence of surgeons, and, he thinks, it might well be in all operating theatres. St. Bartholomew's Hospital, London, in 1885, used it alone in 378 operations; in 1887, used it alone in 417 operations; in 1889, used it alone in 686 operations.

At the present time nitrous oxide is always given by anæsthetists in London before, and along with, the administration of ether. By this arrangement the narcosis is more speedily induced, and the preliminary taste of ether is avoided. It is a luxury, and is suitable for timid people particularly; besides being speedier, it is found to be safer than narcosis by any other plan.

At St. Bartholomew's Hospital, various anæsthetics used during the past fifteen years, were: Chloroform 17,666 times, with 12 deaths, or 1 in 1,472 cases; ether, 7,493 times, with 1 death; gas and ether, 12,806 cases, with 1 death; methylene, dichloride of ethydine, ethyl bromide, ethydine and gas, and various other anæsthetics, 660 cases.

Ether has been usually given by the open method—poured on a folded towel, or one fashioned into the form of a cone.

After referring to various forms of apparatus for giving ether, Dr. Henderson especially commends Clover's, with which, he says, the effects are usually of the best kind. In Leeds, under Mr. Teale, hardly any case is considered unfit for the giving of ether. The patients take it kindly with perfect confidence, old and young are easily and effectually brought under its influence. The old and bronchitic, by judicious management, have only a small quantity of well-warmed ether, and a very little suffices.

The danger from giving chloroform in small doses nowadays is, Dr. Henderson

thinks, the exception. He never hears of the long time of getting the patient under that was not uncommon many years ago. For many years, to push boldly on with the anæsthetic has been the practice all over the United Kingdom, and he says it is wise to do so in threatened vomiting.

But there are cases where A. C. E. or ether is preferable; such as those who have much fear of the operation, or of the chloroform; if the vital powers are weak from great delicacy, or from exhausting illness; if the cardiac, or the pulmonary, or the nervous system is specially sensitive to chloroform; if there is excess of urea in the blood, or of albumin in the urine, or damaged kidneys. One of the difficulties of chloroform anæsthesia is due to the uncertainty of the quantity necessary to induce narcosis. The most recent book on anæsthetics (Foy) gives the account of a patient who was with difficulty recovered from the narcosis produced by three drops of chloroform placed on a piece of cotton wool put into a hollow tooth; and of another, who was narcotized by five drops of chloroform through a Snow's inhaler. Idiosyncrasies such as these may be more common than is supposed, just as some are rapidly and severely affected by small doses of mercury, opium and other drugs.

Dr. Henderson thinks the safest way is that introduced by Mr. Bloxam, of St. Bartholomew's, London. A few drops are sprinkled on a starched towel or flannel cap, and a drop added every second. It is speedily successful in producing anæsthesia, though in some cases it may be a little longer than when it is poured on more freely. He thinks the administrator keeps a better grip of his patient by the drop system.

Four hours before chloroform administration it is well to allow a light, nourishing, easily digested meal. Before ether, no food should be taken for six hours.

Some years ago the nitrite of amyl dropped on lint and held over the mouth was supposed to prevent and recover from accidents. It was also used, mixed with chloroform, as chloramyl, but after a short administration, it was found to lower the blood-pressure instead of raising it. Inhalations of ammonia, in cases of weak or fatty heart, have been found useful, previous to the use of chloroform. Oil of turpentine 1 part, chloroform 4 parts, was believed to prevent pulmonic paralysis. Hypodermic injection of morphia half an hour before the administration of chloroform was supposed to be useful in preventing a fatal issue.

Dr. Bietels, at St. Petersburg, has read a paper on the use of a mixture of chloroform and oxygen. Less chloroform is required than by the usual methods of administration, consequently with less danger, no sickness follows, and the pulse is unchanged. The difficulty is to blend the vapor of the chloroform with the oxygen gas.

Dr. Wood, of Philadelphia, in his address at Berlin, says he found the hypodermic injection of digitalis produced a persistent rise in the arterial pressure, with an increase in the size of the individual pulse rate. In cases of weak heart, where chloroform has to be administered, a dose or two at least of digitalis would greatly lessen the risk of cardiac collapse. The wonder is that this did not occur to us before. Dr. Wood also found the injection of a solution of strychnine into the jugular vein to produce surprising results. It caused a gradual rise of blood-pressure, and always caused an extraordinary and rapid increase in the rate and extent of the respiration. Every one knows the antagonism which exists between chloroform and strychnine. Dr. Henderson would like, however, to have the dose and mode of giving this powerful restorative agent from a scientific authority.

Speaking on the subject of ether administration on the same occasion, Dr. Hartley, of Leeds, assistant to Mr. Teale, suggested the following rules and precautions to be observed in the use of ether were mentioned.

1. As far as possible anæsthetics of all kinds are best given in the early morning when the stomach had been empty for several hours and the body refreshed by sleep; but in any case let no solid food be taken for six hours, nor liquid food for four hours previous to the use of the agent.

2. Avoid giving alcoholic stimulation before administering ether, the effect of this being only to increase the narcotization, and therefore the danger. For a similar reason avoid the use of opium before or very soon after ether.

3. Watch the respiration, the dangers in respect of this function being (1) too deep carbonization of the blood, and (2) mechanical obstruction. The delicate skin of the lobes of the ear is a good index as to whether the patient is becoming too deeply carbonized, and is always open to inspection. Obstruction to respiration may take place from the simple falling back of the tongue;

from the presence of blood, food or foreign bodies in the larynx; from spasm of the glottis; from the accumulation of frothy mucus in the larynx or lungs. If this latter occurs in marked degree, it is often due to the use of too large a percentage of ether vapor in the air breathed.

4. Watch the general character of the circulation, to note the effects of shock, hemorrhage, etc., or a tendency to engorgement of the right side of the heart.

5. Be prepared for any vomiting that might take place.

6. In recharging the inhaler, if this was necessary, beware of the presence or proximity of a naked light, the vapor being very inflammable.

7. Do not use more ether than is necessary to keep up complete anæsthesia.

8. Do not allow the patient's body to be uncovered more than is absolutely necessary for the conduct of the operation. Where a large surface has to be exposed, compensate by extra clothing, hot flannels, hot-water bags, etc., to the covered portions of the body.

As to circumstances which might or might not contra-indicate the use of ether, Dr. Hartley said that he had given ether to people of all ages, from a child of 3 to an old lady of 86, to whom he administered it on three different occasions. No class of cases seems specially prohibitive of ether except patients suffering with acute inflammatory affections of the lung. He had used it in almost all possible operations of surgery, from the extraction of a tooth or the reduction of a dislocation to prolonged abdominal operations of all kinds, operations on the cranial cavity, and in numbers of cases to patients with chest diseases, such as pleuritic effusions, empyema, abscess of lung, sub-diaphragmatic abscess, and in one case to open a suppurating pericardium complicating empyema.

Heart disease does not contra-indicate it. The general effect of ether in the circulation is as a stimulant. In aortic disease this is often beneficial; but if there is a tendency in the venous system to be overloaded and turgescent as in mitral disease, or when the right side of the heart is weak and dilated, or from simple over-carbonization of the blood; then the administration of ether calls for greater care.

Chronic drinkers are bad subjects for anæsthetics of any kind, but specially, perhaps, for ether.

Leprosy in China.

The *Indian Medical Gazette*, November, 1890, says editorially that lepers in China appear to be treated with scant courtesy. Driven from their homes, from their relations and friends, and reduced to a state of destitution, there remains to them but one or other of two things, either to choose to enter the leper villages of China, or to leave the country and seek refuge in some of the adjacent English settlements. Hong-Kong, with no law against the importation of lepers, nor against their begging in the streets, becomes a perfect El Dorado to the leprous Chinamen from the mainland. Dr. Cantlie in a recent paper, read before the Hong-Kong Medical Society, brings this subject prominently forward, and in an interesting and instructive thesis advocates the establishment of quarantine retreats for lepers, who have become British subjects, which he thinks could easily be arranged on one of the numerous islands around Hong-Kong.

In Hong-Kong itself there is an order in force that whenever there is a leper reported, the police shall arrest and detain him until the Colonial Surgeon gives an opinion on his condition, when the leper may be sent away to the mainland. The authorities also at the Native Hospital have power to send lepers immediately they are discovered to some one of the leper villages near Canton. It is impossible, however, to prevent the import of lepers, for, unless by skilled inspection, it is impossible to detect a leper in the earliest stages. Importation of lepers in the early stages of the disease and deportation at a later stage when the ulceration has become so unsightly as to cause the authorities to take action, leave a goodly number of lepers free in the island, and it is this remnant to which Dr. Cantlie would draw attention. He believes with many others that leprosy if it had been communicable only in the later stages, would have long since disappeared, for the unsightly leper with ulcers upon his body has always been studiously shunned. In referring to the manner in which the disease spreads, he attaches much importance to the possibility of house infection, a theory commonly held in Demerara, and mentions the case of a General commanding the troops in that colony, who with his wife and children were attacked with leprosy and died.

It is interesting to learn the Chinese opinion concerning leprosy. They have no

doubts on the subject, being strongly convinced of its communicability and incurable nature. For these reasons they hold that the only manner of dealing with leprosy is segregation, and putting these views into practice, every district in China has its leper home, the inmates of which receive an allowance from the Government, and have land to till. Various forms of treatment have been tried at Hong-Kong. The most successful in mitigating the effects of the disease and in causing improvement in the leprous patches, has been first of all good food and tonics, then the internal administration of chaulmoogra oil in the form of pills, 5 to 15 drops twice a day, and the outward application of the ointment recommended by Dr. Unna consisting of chrysarobin 5 per cent., salicylic acid 2 per cent., ichthyol 5 per cent. When the application was for the face, then pyrogallol was used in place of chrysabrobin, and 10 minims of dilute hydrochloric acid was given three times a day to counteract the deleterious effects of pyrogallol on the blood. The amelioration of the symptoms by this method of treatment is sometimes remarkable, and though no cure has been or is likely to be claimed, yet much might be accomplished in rendering the life of the leper more comfortable by a systematic adoption of this and other similar forms of treatment.

Diagnosis of Paget's Disease of the Nipple.

Surgeons and dermatologists have not infrequently hesitated over a case of chronic inflammation of the nipple resembling in its external appearance an eczema, doubting whether the radical operation of excision of the breast should be undertaken; or, in other words, doubting whether they stood in the presence of what was really chronic eczema, or that affection which long ago Paget taught was likely to be followed by a carcinomatous involvement of the gland. Failure in the ordinary applications for eczema, the absence of itching, suspicious induration and long-standing duration have been the clinical data upon which a diagnosis was usually founded.

Darier, in April, 1889, made a communication to the Biological Society of Paris concerning a new form of *psorospermiæ* found in *Paget's Disease of the Nipple*, describing the parasitic *sporozoa* as occurring inside the epithelial cells of the affected parts. These observations have been confirmed and the whole subject greatly elaborated by Louis Wickham, in his admirable monograph, *Maladie de la Peau dite Maladie de Paget.* According to these authors, the parasitic bodies are found usually in the lower layers of the epidermis of the diseased tissue, and also in the milk-bearing ducts, and measure from one-third to one-half of the stratum muscosum. So impressed is Wickham with these discoveries, that in the conclusion of his essay he states that Paget's disease is due to the parasites of the class *sporozoa*, and the order *coccidia* or *psorospermiæ*, and should be relegated to the group *psorospermosis*. He believes, moreover, that the presence of these bodies, readily detected by microscopic examination of the crusts from the diseased nipple, constitutes an excellent and rapid method of diagnosis.

Further confirmation of these observations comes from Dr. A. B. Macallum (*Canadian Practitioner*, October 16, 1890), who has examined two cases of Paget's disease, and found the bodies in question. In order to avoid disputed points in pathology, Macallum suggests the word *endocyte* as a neutral and readily applicable term to describe these bodies, until their true nature shall be exactly determined. Darier advises that the crust shall be teased out on a slide in Gram's iodine solution and examined with a moderately high-power objective. If fat is present, this may be removed by placing the specimen for several hours in a 10 per cent. solution of ammonia. Macallum modifies this method and secures a permanent preparation by attending to the following directions: The crust, or a portion scraped from the nipple, is teased out in a drop of tincture of iodine on the slide, the cover glass put on, and after a couple of minutes a drop of 50 per cent. glycerine run in. The alcohol and the iodine fix the endocytes, and the iodine gives them a brown-yellow tint, which fades slowly in glycerine. This investigator was thus able to demonstrate these bodies in the free cells, the unteased portions, and in the epithelial cells covering the retracted nipple and filling the ducts. Endocytes present in epitheliomata are distinguishable from these by the absence of cystic membrane, their smaller size and their situation in the central cell of the "nest." Macallum, while unwilling fully to endorse the views of Darier and Wick-

ham, is convinced that the sporozoa furnish a valuable aid in the diagnosis of Paget's disease.

This seems to us a most important field for future work, and not only the diagnostic value of the endocytes, but also their essential nature, are worthy of the careful study which they are at present attracting as etiological factors in various chronic cutaneous disease, and in epitheliomata.—*University Medical Magazine*, December, 1890.

Legislation for Inebriates.

The *Southern Medical Record*, December, 1890, in an editorial, entitled, "A much needed legislation," says: "Now that the representatives of the people are assembled at the capital in the capacity of legislators, it is in order for us to make such suggestions as will more fully acquaint them with our wishes and necessities. Some provision ought to be made for the care-taking and reformation of the unfortunate inebriates of the State. It is a crying shame that nothing has been done in the Empire State of the South to give this greatly needed relief. The world is very uncharitable towards the victims of alcohol. Prohibitory laws have proven a failure; public sentiment is morbid on the subject. Temperance union movements have done much good in educating public opinion, but cannot reach these poor, ruined individuals. What shall be done with them? If inquiry be made, it will show that a large per cent. of the crimes committed—especially the homicides—are due to the effects of whiskey, or some other alcoholic liquor. The sale of intoxicants is licensed and the revenue turned into the public treasury, but there is no provision made to reform the miserable drunkard. Why is this? It is because of the *false opinion* that is abroad that drunkenness is a *sin* but not a *disease*. Such belief obtains only among the uninformed. But we will not stop here to discuss the question. We know whereof we speak when we say that inebriety is one of the most intractable diseases known to the science of medicine. It makes a physical, mental and moral wreck of the individual, unless restored by appropriate treatment. Leaving all other questions aside, we feel that if the State of Georgia would establish and endow an asylum for these unfortunate citizens it will prove a most economic legislation. The cost of keeping and prosecuting criminals, and providing for the insane in the asylum, would soon diminish sufficiently to admit of the establishing of suitable hospitals for the inebriate without any increased expense to the State. Humanity cries out, the heart-broken wives cry out, and the worse than fatherless children cry out for something to be done in this behalf. Legislators have promised to make needed reforms. Here is their golden opportunity. We are confident that Governor Northen will stand by them; that the people will give them their hearty endorsement, and when they return to their homes, it will be said, 'Well done, thou good and faithful servants.'"

Treatment of Gonorrhœa.

The following methods of treatment of gonorrhœa are collected from the *Deutsche Medizinal-Zeitung*, October 16 and 23, 1890.

Friedheim made a careful investigation of the effects of different injections in the dermatological clinic at Breslau. Of mercurial agents the best is hydrargyri salicylatume 1–270. The common astringents, zinc and lead salts, tannin and subnitrate of bismuth, have no antiseptic properties, and should not be used during the acute stage of the disease. Boric acid, antipyrin, resorcin, salicylate of sodium, often influence the inflammation favorably, but are useless as germicides. He uses in the first stages a weak solution of nitrate of silver, about one to three thousand, four to six times a day, later, some milder agent.

Diday uses an injection of nitrate of silver solution, 1–20, and allows it to remain in the urethra from fifteen seconds to two minutes, according to the amount of pain. Picard believes that nitrate of silver will abort a gonorrhœa, and is harmless if given before pus appears; after that it may do harm.

O'Brien uses injections of sea-water seven or eight times a day in the acute stage.

An injection given by Impamlomenti, consists of a one per cent. solution of creasote in an infusion of camomile, with a little boric acid added.

Pyoktanin has been used by several observers with good results.

The ointment-carrying sound of Unna is recommended by several authors for chronic gonorrhœa. Szadek uses an ointment containing nitrate of silver one per cent., and

balsam of Peru two per cent. Sperling and Bender nitrate of silver one per cent. in lanolin. The sound remains at first three, later fifteen minutes in the urethra. For the second stage Lewis uses an ointment with lanolin as a base, and a non-irritating antiseptic, such as resorcin, four per cent.

Allen calls attention to the use of the endoscope, through which a cotton-stick may be used, as a method of application to the urethral mucous membrane.

Internally, Lane obtained good results in sixty per cent. of his cases in from two to seven days, with salol, in doses of from five to fifteen grains, three times a day. In chronic cases injections also must be employed. Dreyfous uses salol at the same time with the balsamic remedies.

Bird has obtained good results by the internal administration of calomel.

Stern recommends a thorough washing of the body in the neighborhood of the genitals, and the patient's clothes, with a one to two hundred solution of corrosive sublimate, to prevent an auto-inoculation, which he considers a common cause of recurrence of gonorrhœal symptoms, and of so-called chronic gonorrhœa.—*Boston Medical and Surgical Journal*, December 4, 1890.

Pyoktanin.

Dr. Riesmeyer has a paper on pyoktanin in the *St. Louis Courier of Medicine*, November, 1890, in which he gives his opinion of pyoktanin after what seems like a fair experience. He says that pyoktanin has the advantage over all other diffusible germicides in not coagulating albumin. It keeps the granulations at an even level, the granulations looking solid and healthy. Wherever it was applied to granulating surfaces, he never saw spongy or exuberant granulations. He adds that it will probably put a granulating surface into an excellent condition for grafting purposes and plastic operations in general. Carbolic acid and iodoform often cause the granulations to be uneven; while the wounds treated with bichloride of mercury frequently have white necrotic deposits. In the granulating wound treated with pyoktanin he observed a rapid reproduction of epithelium at the edge of the wound. Carbolic acid and bichloride of mercury have the disadvantage of often destroying newly formed epithelium, unless the solutions are too weak to combat suppuration effectively.

Dr. Riesmeyer's observations in the cases so far treated lead him to surmise that the chemical composition of pyoktanin is changed by some substance in the animal tissues, or it may form new combinations which are colorless and do not stop the growth of bacteria, and that the failures in arresting certain forms of suppuration, probably all those where the micro-organisms are located deeply in the tissues, is due to this property. Dropped on the skin or mucous membranes, the stain produced will soon disappear, showing that here also must be an agent present, which produces a change in its composition. In order to see whether albumin had anything to do with this change, he placed a silk thread stained with pyoktanin blue, about $\frac{1}{2000}$, in the white of an egg. In 24 hours the thread had lost its blue color, and no trace of pyoktanin could be seen in the white of egg. Since, however, the white of egg contains other substances besides pure albumin, this experiment may not count for anything.

It will be of importance to know whether, when pyoktanin is injected hypodermically into diseased tissues in as concentrated solution as possible, it will destroy the micro-organisms before it undergoes the change referred to or not. No doubt this point will soon be cleared up by experimental research.

At the present time we are not able to formulate its exact indications in surgery with any degree of accuracy, since the technique of its application is still in its infancy. In certain selected cases it will be of excellent service, but on account of the change it seems to undergo in the tissues, and also on account of its annoying staining properties, Dr. Riesmeyer is inclined to think that the limit of its usefulness in this branch of medicine will be rather narrow in comparison to the hopes that its germicidal properties in the test-tube have inspired.

Immunity from Diphtheria and Tetanus.

Dr. Behring has made known the chemical agent employed by him and Dr. Kitasato in their experimental investigations on diphtheria and tetanus. This is trichloride of iodine, which, injected subcutaneously in animals inoculated with either virus, not only cures them, but renders them immune to subsequent infection. Peroxide of hydrogen in 10 per cent. solution can also confer such immunity in respect of diphtheria.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few para graphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspaoers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE KOCH REMEDY FOR TUBERCULOSIS.

It is now about two months since Koch made the announcement of his "remedy" for tuberculosis, and it may be said to have had a fair opportunity to show what it would accomplish. Of course there has not been time to show cures without possibility of recurrence—years might not suffice for this; but there has been plenty of time to show if it could produce improvement of steadily progressive character and furnish ground for hope that eventually some form of tuberculosis would be—in a fair sense of the term—cured through its influence upon the human economy.

The readers of the REPORTER have been given, in a series of carefully prepared special articles, an account of the experiments made with the "lymph" in all parts of the world, with their results, and the opinion of men of recognized ability in regard to the value of it.

Unfortunately after all it is impossible to say that the lymph can be relied upon for any of the purposes indicated by Koch in his first announcement. It is not a trustworthy means of diagnosis, or a reliable remedy for any form of tuberculosis; while experience has demonstrated that it is dangerous when used either for diagnosis or for treatment.

Professor Virchow, who has been making investigations on the lymph treatment, last week asserted, after twenty-one *post-mortem* examinations of patients who had died after injection, that the Koch method is not what had been hoped or claimed for it, and that there can be no permanent benefit from it to the patient. The tubercle bacilli he says are not killed by the lymph, but are only driven out to take lodgment elsewhere. Thus, according to his theory, tuberculous affections, while they may disappear from one part of the body, break out in other places in as discouraging a form as ever. To this we may add that the phenomena of certain cases, in which it has been asserted that unsuspected tuberculosis of the lungs had been revealed by treatment with the lymph, warrant the belief that the lymph may set up a tuberculous process in persons entirely free from disease.

The REPORTER has, as stated above, contained a very carefully prepared synopsis of the developments in connection with the testing of Koch's "remedy," and the readers of the REPORTER will be promptly informed of any developments in connection with the subject; but we doubt that it will require as much space as has been devoted to it in the last four issues, for it seems hardly worth while to continue the weekly publication of accounts which are so largely mere repetitions of fruitless or injurious experiments on human subjects.

Furthermore, we believe the time has come when such experiments ought to be discontinued, or at least restricted to a very

small sphere. In this country we think they ought to be wholly abandoned. Last week a large number of tuberculous patients in the Philadelphia (Alms House) Hospital refused to submit to be experimented on, and although the physicians with the lymph from Koch's laboratory were chagrined, we cannot believe all of them thought the patients were unwise.

We would suggest that American patients be allowed the benefit of such medical and surgical skill as exist in the profession until the Germans have shown that Koch's "lymph" is really of use. Let the latter do as much experimenting as they may consider wise and right; but let our countrymen go back—those who left them—to the legitimate methods practiced before it was heard of.

It is with regret for the disappointed expectations against which we warned our readers two months ago, that we suggest to them to read again and carefully the Editorial in the REPORTER of November 15, 1890, and to reflect on the confirmation of its statements which has been supplied by the history of Koch's "remedy" since that Editorial was published.

CANCER GERM.

For several years bacteriologists have been studying the tissues and secretions of each of the most important diseases in the hope of finding some germ which may possibly be the essential cause of the disease. The interest at present felt in this kind of study is widespread and intense. Doubtless hundreds are at this moment at work upon the pathology of cancer, and are endeavoring to discover its cause. Many of those who fail to find any germs in cancer will think it not worth while to report their investigations; but a number have already announced what they believe to be discoveries of germ life in cancerous growths, although no one has hitherto succeeded in demonstrating the supposed germs to the satisfaction of others, still less has any one succeeded in tracing a causal connection between any particular micro-organism and cancer. In the *Deutsche Medizinal-Zeitung*, November 20, 1890, Dr. J. E. Alberts gives a very thorough review of the present condition of the cancer question and of its most recent and important literature. Dr. Alberts's own experiments have not been insignificant. He injected dogs with a sterilized emulsion of cancer-juice, prepared aseptically from a carcinoma removed from a living person. The result was entirely negative; the animals lived for months healthy, and at the autopsy nothing was found by macroscopic or microscopic examination, except a trace of the injection wound. Results of transplanting pieces of recently removed carcinoma were just as fruitless; recovery from the operation occurred, and at a subsequent autopsy nearly all of the transplanted piece had been absorbed. Other investigators, particularly Darier, Albarran, Thoma, Wickham and Sjöbring, have described, with more or less precision, a parasitic organism which they have found in cancer. An interesting fact about their descriptions is that all the writers named, except Thoma, who expresses no opinion, speak of the organism as belonging to the protozoa.

The most recent article on the subject of an organism found in cancer is by Dr. William Russell, Lecturer on Pathology in the Edinburgh School of Medicine, and is published in the *British Medical Journal*, December 13, 1890. Dr. Russell writes that he has been occupied for several years in tracing the mode of growth of cancer in different organs. In the course of these studies he met with appearances which he could not fit into modes of cell-growth and nuclear proliferation. He was finally able to differentiate them by a process of double staining with fuchsin and iodine green, the latter replacing the former in everything except the bodies in question. Although these bodies were found in practically every case of

cancer examined, Dr. Russell determined to eliminate all possible sources of error before coming to any conclusion with regard to them. To this end, he ascertained, by check experiments, that they were not produced by accidental impurities in his materials, bottles or stains, nor by a trick of staining; that they were not nuclei of tissue-cells in exaggerated, formative and reproductive activity; and that they were not globes of some form of degeneration. Dr. Russell examined with great thoroughness and apparent fidelity all kinds of tissues and disease products to see if he could discover these "fuchsin bodies," as he calls them provisionally, in anything but cancer. He found them in one case of supposed sarcoma; in two old specimens, one of adenoma of the mamma and one of gumma of dura mater; in one case of syphilis in which, some six or seven weeks after primary infection, there was only a skin eruption but extensive destructive lesion of the fauces and larynx, and even of the bones of the vertebræ behind the fauces; and in a polypus from the ear, which consisted in greater part of fibro-myxomatous structure, but was in its deeper part adenomatous, and it recurred *in loco* after removal; in one case of gelatinous degeneration of the knee-joint, with old sinuses; and in a large, very intractable ulcer of the leg. Tissues were examined from fifty or sixty different cases in all.

On the other hand, forty-five cases of cancer were examined, and in forty-three the fuchsin bodies were found. As a rule, they occur in clusters containing from three to twenty or more. Wherever they occur they almost always show a clear space around them. They can, Dr. Russell says, be found readily with a lens of one hundred diameters if the light is good; their brilliant red or purplish color forms a striking contrast with the green and delicate purple of the tissues. The individuals of which the groups consist are in form perfect spheres, the largest being half the size of a red blood corpuscle. They appear perfectly homogenous and structureless as examined by daylight, and the larger clumps are held together by a delicate cementing substance which stains faintly. From a careful study of these fuchsin bodies, Dr. Russell says he has absolutely no doubt that they are organisms belonging to the sprouting fungi, a class of fungi which includes the yeast plant.

Dr. Russell's observations are of very great interest, and seem to have been made with great care. If they are confirmed by other pathologists, and these fungi are found to be the invariable accompaniments of cancer, it will remain for some one to prove their relation to the cause of the disease. This can be done only by inoculating animals with pure cultures, and thus producing cancer, which must contain the same fungi, capable of cultivation. At present bearing in mind Scheuerlen's announcement of a bacillus of cancer, and its subsequent fate, we can only suspend judgment and wait for further light.

THE AMERICAN MEDICAL ASSOCIATION.

In an organization like the American Medical Association the management is naturally controlled by those who attend its meetings regularly and who take the most active interest in its government. Ordinarily this fact enables members who have no desire for office or emolument to enjoy the privileges of an association without bearing the burdens or meeting the cares of office, while these fall to the lot of those who think the pleasures or advantages of office more than compensate for them, and the organization goes on smoothly and prosperously under this arrangement.

But at times it is desirable for every member of an association to consider carefully the policy of the organization to which he belongs and the purposes of those to whom its management has been delegated, and to inquire if they be what is best for the or-

ganization. Such an occasion has just arisen in the American Medical Association, and it has been precipitated by the proposition of certain of the Trustees of the *Journal of the Association* to transfer its place of publication from Chicago to Washington. This proposition is so radical and of such consequence to the prosperity of the *Journal* and the welfare of the Association that it ought to be most carefully considered between this and next May when the Association meets. A right decision of it is of the utmost importance, and to this we invite the thoughtful attention of all the members of the Association.

It might be well to have the subject discussed in the various County and other Societies which send delegates to the Association, and that these should instruct their delegates how to vote on the proposition.

We speak of this because of our conviction that an error committed now would very seriously impair the usefulness of the Association, and our hope that no error may be committed.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

FAMILIAR FORMS OF NERVOUS DISEASE. By M. Allen Starr, M. D., Ph. D., Professor of Diseases of the Mind and Nervous System, College of Physicians and Surgeons, New York. With illustrations, diagrams and charts. 8vo, pp. xii, 339. New York: William Wood & Company, 1890. Price, $3.00.

Dr. Starr, in his preface, calls attention to the advances in neurology, which he believes have been of late more rapid than those in any other department of medicine. The result, he says, has been to render diagnosis both easier and more precise, and to open to surgical treatment many diseases formerly considered fatal. The object of the present volume is declared to be to make available to the general practitioner some of the results of later investigations which have a direct and practical bearing upon commoner forms of nervous disease. The facts which Dr. Starr seeks to emphasize are such as enable one to make an accurate diagnosis of the nature and of the location of lesions of the central nervous system. The book is not intended as a treatise on nervous diseases, but as a series of clinical studies of their more familiar types. The first eight chapters are taken up with the localization of cerebral functions; the functions of the cortex and of the motor, visual and cortical areas, and the tracts within the brain, and with the diagnosis of sub-cortical lesions. Chapters ten, eleven and twelve deal with localization of diseases of the cord, and the following chapters successively with the paralyses of infancy, multiple neuritis, paralysis agitans, chorea, epilepsy, some painful functional affections and their treatment, the treatment of neurasthenia, the ordinary forms of insanity, and a final section on electricity as a therapeutic agent.

In the treatment of epilepsy Dr. Starr uses a combination of the bromides of potash, soda and ammonia, with the addition of a small amount of arsenic and an alkaline potash salt. In cases of nocturnal epilepsy he recommends giving also five or ten minims of the fluid extract of belladona or $\frac{1}{120}$ of a grain of atropine at bed-time. He says that chloral is sometimes a helpful adjuvant, and so is tincture of simulo. Every patient of Dr. Starr who has an aura is furnished with a small bottle containing cotton saturated with nitrite of amyl. In about one-fourth of the cases this when inhaled aborts the attack.

Of electricity as a therapeutic agent, Dr. Starr says: "My experience coincides with that of Gowers, that the therapeutic effects of electrical applications have been much exaggerated and are really quite limited."

The book shows that the author has obtained all the light possible from experimental physiology and pathology, and that he has checked those results by careful clinical observation; as a consequence, he has produced a thoroughly trustworthy, and a very interesting volume.

L'INTOXICATION CHRONIQUE PAR LA MORPHINE ET SES DIVERSES FORMES. Chronic Morphine Poisoning, etc. By Dr. L. R. Régnier. 8vo, pp. 171. Paris: Office of the *Progrès Médical*, 1890. Price, 3 francs 50 centimes.

Régnier credits Nussbaum, in 1864, with the first observation showing the evil effects of prolonged injections of morphine. Since then important works have been written by Lewenstein, Erlenmeyer, and others. Régnier examines particularly the symptoms evoked by chronic morphine poisoning. He finds that morphine produces modifications of sensibility, anæsthesia in hyperæsthesia, while the sense of touch is often lessened in delicacy or perverted. Paralyses are rare, but vision is often affected, and the memory, judgment and will are lessened in some patients to such a degree that they fall into true dementia. It would appear that when pain exists and morphine is used to overcome it, the evil results are less serious, and that, when the patient dies, it is from the progress of the disease causing the pain, or from some intercurrent affection. Also, according to Régnier, morphine habitués who are content with moderate doses may live well for long years with their poison without being inconvenienced except by more or less considerable emaciation, by constipation, and by a certain degree of apathy.

Those who become addicted to the habit from the desire for a stimulant appropriate to their fancied needs Régnier described as morphinomaniacs and "morphinomania" is the title of the second division of the book. The recent morphinomaniac, Régnier says, is likely to become a proselyte-maker among his friends, who may be led to try the drug out of curiosity, and then, as Landowski says, there is "one morphinomaniac more."

The disease appears to be of more frequent occurrence in men than in women. Its various and progressive stages are well described by Régnier, who

reports sixty-seven case in illustration of the points raised. As to treatment, he says that in inveterate morphinomaniacs one cannot count much upon the efficacy of treatment. When treatment succeeds, the recovery is not ordinarily maintained. Immediate and complete suppression of the use of morphine, he says, is not always possible, and its effect ought to be watched attentively in inveterate cases. Complete and final recovery is rare and can be hoped for only in those whose passion for morphine is of recent date and who do not have any hereditary defect.

A good bibliography is appended to Régnier's book, which is a valuable contribution to the literature of an extremely important subject.

Literary Notes.

—The *Illustrirte Monatschsrift der Aertztlichen Polytechnik*, which brings each month a most interesting summary of new inventions in medical and surgical appliances and advances in the treatment of deformities, will begin the year 1891 by uniting with the *Fortschritte der Krankenpflege*, and will hereafter be published by Fischer's publishing house in Berlin, The union is one which promises increased interest and usefulness for both journals.

—Rudyard Kipling contributes the complete novel, "The Light that Failed," to the January number of *Lippincott's Magazine*. Kipling is attracting more attention at present than any other living writer. His force and originality have taken the world by storm. "The Light that Failed" is his first novel and fully justifies the expectations he has raised by his remarkable short stories. It is the story of an artist's life and love, and Kipling shows that he fully understands an artist's outlook upon life, and his hopes, expectations and fears. It is his comprehension of the inner and outer life of men, and his ability to portray both, that is the secret of Kipling's power. In him what is called realism and idealism are blended.

—The first number of the *Balneologisches Centralblatt*, dated October 3, 1890, is at hand. It is a journal in appearance like the *Centralblatt für Chirurgie*, and that *für Medecin*, with which all medical readers of German are familiar. It gives promise of being an interesting and instructive journal on its subjects—balneotherapy, hydrotherapy, massage, gymnastics, etc. It is issued every two weeks by B. Konegen, in Leipsic, and the price is five marks each six months.

Special Article.

KOCH'S REMEDY FOR TUBERCULOSIS.

A RESUMÉ OF ITS HISTORY.

[*Continued from page 51.*]

Dr. Saundby and Messrs. Simon and Barling, in the *Birmingham Medical News*, Dec. 1, 1890, give a very moderate account of their impressions of the value of the lymph, as seen in use at Berlin, where they had an opportunity of watching the treatment of a number of cases of laryngeal and pulmonary phthisis under the care of Professors Fraentzel and Senator in the Charité Hospital, under Professor Ewald in the Augusta Hospital, and under Dr. A. Levy at his private Clinic. They saw "no case that could be regarded as cured, and in some improvement was doubtful, but others expressed themselves as feeling decidedly better, and there was evidence of this in the cessation of night-sweats, diminished cough and expectoration, and increase of weight." They point out that it is common in cases of phthisis for the patients to lose weight in the early stages of the treatment, but this loss is more than made good later on. With regard to lupus, the authors say that whatever may be the future fate of the patients whom they saw, there could be no doubt that at the time they were remarkably improved, while in some cases no active disease could be detected. In tuberculosis of lymphatic glands they were also able to observe considerable improvement also. With regard to joint disease, they saw instances in which there had evidently been distinct improvement; but none in which a cure had been effected.

The *British Medical Journal*, December 20, quotes a report on the Koch's Treatment in Leprosy, in the *Semaine Médicale*, December 10, of a patient presenting the characteristic signs of leprosy, shown by Dr. Max Joseph at a meeting of the Berlin Medical Society on November 26. He had a well-marked leonine countenance, but there was no ulceration of the face. He was treated with injections of Koch's fluid, and in a short time the chin and the nose became covered with little crusts very close together. Each of these scabs covered a tiny ulcer of about the size of a pin's head. The crusts were exactly like those which are formed on the surface of a lupus patch during the period of reaction. There was no fever or other sign of general reaction. The diagnosis of leprosy was confirmed by microscopic examination of a piece of skin excised from the chin a few days before the injections were begun.

The Berlin correspondent of the *Lancet*, December 20, 1890, gives an account of a patient with tuberculosis of the larynx, treated by Gerhardt, on whom tracheotomy had to be performed to prevent imminent death due to closure of the chink of the glottis.

The *Journal de Médicine*, December 14, 1890, says: Seventeen deaths in Germany, four in Austria and one in Paris—such is the account of Koch's method during the week just ended.

In the *Revue de Laryngologie*, December 15, 1890, Baratoux gives a careful resumé of the operations of the lymph thus far—especially from the standpoint of the laryngologist. As to its diagnostic value he calls attention to the uncertainty of the reaction and the fact that non-tuberculous patients manifest it—persons with leprosy, syphilis and scarlatina, while persons with tuberculosis laryngitis do not always show it. Its curative properties he regards as still less worthy of confidence. The ameliorations noted are in no sense greater than are observed under other methods of treatment, while the lymph seems to give rise to ulceration and the development of acute miliary tuberculosis—in one case he speaks of the inoculation as having advanced the course of the disease six months. The reasons he gives, he says: "compels a reserve more than justified for this method of treatment which after all has given no results, but which facilitates the increase of the malady and even, it is said, the development of latent tubercles, and perhaps even of those which did not exist before."

One of the most important communications in regard to the Koch remedy is that of Dr. Williams, of the Brompton Hospital for Consumptives, in London, in the *British Medical Journal*, December 20, 1890.

It is a curious spectacle, he says, and one by no means flattering to the votaries of science, to see the medical world of Berlin given up wholly to the worship of "Koch's injection" and "reaction process," and all the usual pathological and clinical phenomena of tuberculosis set aside to make way for the one newly-found distinction of reaction or non-reaction after lymph injection. He visited nearly all the clinics containing cases of phthisis, and examined about 100 in whom the disease dated from months to years, and whose lungs showed great diversity in the extent the lesions present. There was no lack of opportunity of studying phthisis in the Berlin hospitals, for the city was fast becoming the receptacle of the phthisis of Germany, and even of some neighboring countries, to the exclusion of other diseases. The Moabit Städtliches Hospital of 700 beds already contained a large proportion of consumptives, some of whom are under the personal observation of Professor Koch. The most striking effects of the injection were in laryngeal phthisis, where, with the reaction, swelling of the mucous membrane, and separation of grayish sloughs are visible under the laryngoscope, and, according to Professor Krause, both exfoliation and reabsorption of the swelling take place. Improvement in laryngeal phthisis is common, but complete cure rare.

The great mass of the cases of phthisis were such as may be found in Brompton and in other chest hospitals—partly cases of tuberculization, partly cavity cases, though the conditions of hospital life are in many respects different. The chief symptoms in consumptive cases appeared to be rapid rise of temperature (reaching 103°, 104°, 105° and even 106° F.), quickening of pulse and respiration, the latter being especially marked, occasionally vomiting, increased cough and expectoration, with inspiration of the latter, often aphonia from temporary laryngeal catarrh. In some cases a scarlatinal rash has appeared, and in others (though generally lupus cases) a papular eruption, as Dr. Williams witnessed in two patients. In a few the nervous system appears much affected, as one patient became almost melancholic, and another perfectly unconscious after injection. The whole of these symptoms pass off in a few hours, and the patient returns to his ordinary state till the next injection. This is repeated the next day or in a day or two with increased dose, and continued till all reaction ceases, when the tubercular disease, as far as active tuberculosis is concerned, is held to be arrested.

Nevertheless cases occur which cease to react under strong injections but still present the physical signs of phthisis and whose sputum contains tubercle bacilli. The existence of a reaction after injection is said to prove unmistakably the presence of tuberculosis, and Professor Koch informed Dr. Williams that if a patient, after successive injections, reached the centigram dose without reaction he could be held free from tuberculosis. This may be so. But Dr. Williams examined in one of the clinics a middle-aged man, with a well-marked cavity in the upper lobe of the right lung of some standing, with marked fibrosis of the rest of the lung and with some necrosis of the sternum, the supervention of which had relieved the cough, expectoration and other lung

symptoms. The sputum contained no tubercle bacilli. This patient gave no reaction after strong injections. As an example of the extent to which the reaction test is pressed Dr. Williams gives the following account.

A young man, with a history of cough and expectoration, was injected with a moderate dose. He had no physical signs or tubercle bacilli in the sputum. No reaction following, the injection was repeated after a few days' interval. Still no reaction. A third and somewhat stronger injection was followed, however, by a decided reaction, the temperature reached 102.2° F., crepitation sounds were audible at one apex and tubercle bacilli detected in the sputum. This case was shown to Dr. Williams as a proof of the value of the injection as a means of diagnosis, but, he says, if the lymph is, as is generally believed, some form of a cultivation of the tubercle bacillus from which the bacilli are removed, there might be other ways of explaining these symptoms, which were, to say the least, very important.

The influence of injections on the tubercle bacilli in the sputum, was, as far as Dr. Williams could gather from the records, not very marked.

Two *post-mortem* examinations on cases dying of phthisis in the Charité Hospital, which had been submitted to the treatment, and had received several injections, showed in one case cavities of considerable size, and in the other a cavity at one apex, pneumonia at the base, with a large eruption of recently-formed tubercle. In neither case was there any sign of cicatrization or fibrosis, nor of more necrosed masses than are usually to be found in similar cases.

The great portion of consumptives under the treatment appear to lose weight rather than gain, presumably on account of the fever reaction; the cough and expectoration seem lessened, but no solid improvement appears to be gained; this, however, only applies to the patients who have been under the treatment two or three weeks, which is the case of the majority.

A few old cases from Professor Fraentzel's clinic, and some which have been in Dr. Levy's, and are now in the Moabit Städtliches Krankenhaus give better results. He speaks of eight cases, which, with a few in Professor Ewald's clinic, were all he could collect as examples of genuine improvement under the Koch treatment, out of about one hundred examined by him. The improvement, though striking, he says, was not more than is met with in the wards of the Brompton and other consumption hospitals under the ordinary conditions of diet and treatment, and he adds that they would not for an instant compare with the results obtained at the high altitude sanitoria, such as Davos, St. Moritz or Colorado, where the restoration to health is often complete, and no physical signs or tubercle bacilli remain.

Dr. Williams thinks that the Koch treatment is worthy of a careful and prolonged trial in proper sanatoria, with the addition of pure air and good food and careful nursing. In conclusion he says: "We owe much to Professor Koch, and it is only due to the great services which he has rendered to medicine that his treatment of phthisis should have a fair, full and impartial trial; and this will be easier and more willingly undertaken when he has imparted to all scientific workers the complete details for preparing the lymph."

Notes and Comments.

Treatment of Phthisis.

Dr. Heneage Gibbes has an interesting paper on the question of the unity of phthisis in the *Boston Medical and Surgical Journal*, December 25, 1890. In this he says: I presume no one will doubt that Dr. Koch has entire belief in the unity of phthisis and its bacillary origin. It is, therefore, with some surprise that we read the statement that his lymph does not kill the tubercle bacilli but the tuberculous tissue, that it can influence living tuberculous tissue only, and has no effect on dead tissue, as, for instance, necrotic cheesy masses. This at once removes from its action all cases of pulmonary phthisis, and leaves only tuberculosis to be acted upon.

As I have already pointed out, we have in tubercular tissue a new formation of low vitality, which is shown by its proneness to break down. We have a somewhat similar tissue in the lesions of syphilis; and we know that under the influence of certain drugs, these lesions will soften and caseate. But the tissue found in syphilis is of a much softer, less organized, and more unstable character than that found in tuberculosis. Koch's remedy is said always to cause a feverish reaction accompanied with rigors, when inoculated in a patient, the subject of tubercu-

losis; and this symptom is absent when the case is one of syphilis, cancer, or any other disease. The most marked success so far, seems to have been obtained in cases of lupus, and here the parts affected showed a reaction to the remedy by becoming red and swollen. Whatever may be the future of Koch's cure, one thing seems to be certain, and that is it will not help cases of pulmonary phthisis. This will necessitate our making a careful diagnosis in every case, as fortunately we are able to cure pulmonary phthisis in the early stages by ordinary remedies, and, as Dr. McCall Anderson has shown, even cases of galloping consumption, provided they are not tubercular.

One of Koch's statements is difficult to understand; it is, that his lymph destroys the tubercular tissue in which the tubercle bacilli are situated. Now, given a lung studded with tubercles, all of which are suddenly killed by the action of the curative lymph, it does not seem clear what is to become of the necrosed material. We know that a syphilitic gumma, after it has been destroyed by the action of a drug, will still remain as a foreign body in the part, and set up chronic inflammatory action; in this manner forming a fibrous capsule and isolating itself from the surrounding healthy tissue. The same thing may be done by a tubercle or a nematode worm. The centre is a mass of caseous material having no structure to show what it originally consisted of; it becomes, however, completely isolated by a fibrous capsule formed by the chronic irritation of its presence. The central portion may undergo calcification.

If Koch's lymph kills the tubercles in a diseased lung, what change will take place in them? If they are to be softened and absorbed, the place they occupied will be left vacant and the lungs full of holes, as they were formed at the expense of lung tissue. If, on the other hand, they are simply killed, and dry up like a dead gumma, the lung will in time be filled with numbers of small fibro-cystic masses. We need more light upon this subject; but before all things, it seems to me, we ought to have a clear idea of the actual lesion in the lungs to enable us to appreciate the action of the cure.

It may be of interest to the Society to hear a short account of the work that Dr. Shurly and I have been doing during the last two years on this subject. We came to the conclusion that the lesions in the lungs must be formed by some morbid product circulating in them; and it seemed to us that the only way, if our views were correct, in which this disease could be checked was by the introduction of some substance which would enter into chemical combination with the morbid product and render it inert. We have never made any attempt to destroy the tubercle bacilli.

It is now more than two years since our first experiments were made, and they have been continued ever since. After trying a number of different substances we found that with iodoform we could entirely check the tubercular process in an inoculated animal. We inoculated monkeys and guinea-pigs with tubercular material; and we found that those treated with iodoform developed nothing further than an abscess at the seat of inoculation, with numerous tubercle bacilli in the contained pus, while the control animal, in each series, left untreated, invariably died of the disease. But we found that the use of iodoform brought on fatty changes in the liver, of a peculiar character, consisting of an infiltration in patches and not like that found in ordinary fatty liver. These patches were not confined to one or more lobules; but at the edge of the patch, in many cases, only a part of a lobule was changed.

While Dr. Shurly was treating the inoculated animals with various drugs, I made a series of experiments on pure cultures of the tubercle bacilli; and I found a number of drugs which would render them inert, as far as their power of producing artificial tuberculosis was concerned. Among these, chloride of gold and sodium exerted a marked influence when used in very small quantities; and Dr. Shurly will tell you what a striking effect it has when used on cases of consumption. As soon as we found that we could prevent the development of the disease in inoculated animals, Dr. Shurly directed all his attention to finding a substance which could be used on human patients without deleterious effects; and I investigated the results of the various inoculations with a view to proving that tuberculosis and pulmonary phthisis reproduced themselves in a different manner in susceptible animals. In both these lines I think we have been successful, although it will require further investigation before we can consider the matter definitely proved.

I should like to call attention to the effect of Dr. Shurly's treatment upon the sputum of the patients. He has kept me

regularly supplied with sputum from all cases under treatment; and I have found that those cases treated with substances that produced a marked amelioration of the disease had little or no effect when inoculated in animals. I have a number of guinea-pigs inoculated with sputum from undoubted cases of consumption; and these guinea-pigs are now none the worse for the operation, which was done some months ago.

That a marked change has taken place in these consumptive cases is shown by the total disappearance of bacilli in most of them.

Experiments in Regard to Rabies.

Protopopoff states, in an article in the *Zeitschrift für Heilkunde*, of which an abstract is given in the *Centralblatt für Chirurgie*, October 18, 1890, that, apart from the now disproved theory of phagocytosis, there are two opposing explanations of immunity, the exhaustion theory, and the antidote theory. Protopopoff acknowledges himself to be an adherent of the latter theory, for which he brings new proof in his experiments. Before giving the results of his own experiments, he presents a thorough historical review of the development of the question, which is in the main a review of the works of the French authors, Pasteur and Toussaint, but especially of Chauveau—the first defender of the antidote theory—Roux and Chamberland, Chantemesse and Widal.

Protopopoff's experiments, conducted during the last two years, were undertaken for the purpose of investigating whether or not protection against Pasteur's disease (experimental rabies) depends exclusively upon the action of Pasteur's so-called vaccine material, or virus, and therefore upon purely chemical changes. Pasteur has assumed for immunity against rabies that in protective inoculation, together with the microbes a special substance (vaccine) passes into the body, and that under certain circumstances this opposes the outbreak of the disease.

Protopopoff, took the spinal cords of animals which had died of rabies, and removed from it the fixed virus by sterilization. He found that placing such cords in glycerine bouillon at a temperature of from 65° to 68° Fahr., for from fifteen to twenty days, accomplished this purpose, and that an emulsion prepared with spinal cords treated in this way can be used as a sterilized culture of the virus.

In his confidence in glycerine he is in direct opposition to Gibier, the most conspicuous disciple of Pasteur in this country. But as Protopopoff is an extremely careful and trustworthy investigator, it may be assumed that he is correct in what he says.

A series of further experiments and control experiments by Protopopoff showed that immunity against experimental rabies could be secured by inoculating animals with the non-poisonous emulsion just described. Out of nineteen dogs protected by inoculation with Protopopoff's sterilized virus, fourteen were proof against the usual effects of inoculation with the virus of Pasteur's disease—so-called rabies; while every one of the fourteen animals used for control experiment—that is, inoculation with virus of Pasteur's disease, without previous protective inoculation—died.

Protopopoff further suggests that the outbreak of experimental rabies can be prevented in cases in which infection has occurred before inoculation.

Death in a Dentist's Chair from Cocaine Injections.

The *Journal für Zahnheilkunde*, Sept. 25, 1890, reports a case of death in a dentist's chair from injections of cocaine into the gum, given for the purpose of inducing anæsthesia for the extraction of roots of teeth. The patient was a woman, twenty-nine years old, apparently perfectly healthy but very nervous. The extraction was painless, and nothing abnormal was noted. The operator withdrew from the patient's chair to get some water for the patient to rinse her mouth with, and on his return found her motionless. Physicians were summoned and artificial respiration was practiced, but without success. The autopsy disclosed the fact that three injections had been given, which served for the extraction of three roots. The quantity of cocaine in each injection was two centigrams, or one-third of a grain. The *Journal*, after commenting upon the dangers of cocaine, refers to nine cases of fatal poisoning reported by Dufournier, in the *Archives générales de Médecine*. One of these cases, however, is doubtful, as the patient took a mixture of chloral and cocaine. None of them happened to dentists, and the *Journal* thinks the case it reports the only fatal one occurring in the practice of a dentist. This may be true,

but serious and well-nigh fatal cases undoubtedly have occurred. The *British Medical Journal*, Feb. 9, 1889, p. 311, refers to one in which one grain and a third of cocaine was used.

To show how uncertain the action of cocaine may be, a case may be mentioned in which one-seventh of a grain injected into the eyelid produced very serious poisoning. The case is reported by the *British Medical Journal*, in the article already referred to. It would appear not to be safe to inject a larger quantity than one-half or three-fourths of a grain, especially into very vascular tissues, from which absorption is likely to be rapid and the consequent danger of a maximum effect upon the heart is greatest.

Tiliacin.

The *Druggists' Circular*, December, 1890, says that the isolation from the leaves of the lime tree of a new glucoside, to which the name tiliacin has been given, is announced by Professor Latschinow (*Chem. Zeitschrift*). It is described as splitting up into glucose and tiliaretin, which again decomposes into anisic acid and other products. The leaves of *Cirsium arvense* appear to contain the same glucoside, whilst a glucoside from the leaves of *Phlox paniculata* appears to differ from both tiliacin and hesperidin.

State Medical Society of New York.

The eighty-fifth annual meeting of the Medical Society of the State of New York, will be held February 3–5, in the City Hall at Albany. The following scientific business is announced.

For Tuesday, February 3, the President's Inaugural Address, and papers on Railroad Surgery, by Clinton B. Herrick, Troy; Report of Cases of Injury to the Knee Joint, with Remarks, by Henry Flood, Elmira; Management of Sinuses in Chronic Bone and Joint Diseases, by V. P. Gibney, New York; Necrosis of the Ribs, Complicating Pott's Disease, by Louis A. Weigel, Rochester; Brief Notes on Gastrostomy, with Report of a Successful Case, by Charles A. Powers, New York; The Action of Trypsin, Pancreatin, and Pepsin, upon Sloughs, Coagula and Muco-pus, by Robert T. Morris, New York; Operative Procedures in Acute General Suppurative Peritonitis, by W. E. B. Davis, Birmingham, Ala.; The Progress of Cystoscopy in the last three years, by Willy Meyer, New York; A Plea for Rapid Dilatation, Holt's Operation, in the Treatment of Urethral Stricture, by F. R. Sturgis, New York; A Case of Imperforate Anus of eight weeks standing, Operation and Recovery, by Wm. Hailes, Jr., Albany; Diagnostic Significance of the State of the Pupils, by E. C. Spitzka, New York; Three Diagnostic Symptoms of Melancholia, Second Communication, by Landon Carter Gray, New York; Hysterical Manifestations Due to Alcoholism, by H. C. Coe, New York; Cases of Traumatic Hysteria, by Henry Hun, Albany; Insomnia and its Treatment, by E. N. Brush, Philadelphia; Causes of Asthenopia, by D. B. St. John Roosa, New York; Treatment of Detachment of the Retina, by David Webster, New York; Use of Platinum Instruments in the Extraction of Cataract and in Other Operations upon the Eye, by E. Gruening, New York; Contagion from Roller Towels, by Lucien Howe, Buffalo; One Thousand Cases of Ocular Headache and the different States of Refraction connected therewith, by W. F. Mittendorf, New York; Catarrh and its Cure, by O. B. Douglas, New York; On the Causes of Eczema, by L. Duncan Bulkley, New York; Points in the Pathogenesis of Aural Vertigo, by Oren D. Pomeroy, New York; Certain Hygienic Measures in the Treatment of Catarrhal Affections of the Upper Air Passages, by F. H. Bosworth, New York; Contribution to the Surgical Treatment of Jacksonian Epilepsy, Excision of the Arm Centre, by Edward B. Angell, Rochester.

In the evening there will be a discussion on Appendicitis, the subject being divided as follows: Pathology of Appendicitis, by Herman Mynter, Buffalo, and Arpad G. Gerster, New York; Indications for Early Laparotomy in Appendicitis, by Charles McBurney, New York, and William W. Keen, Philadelphia; Technique of Operative Interference in Appendicitis, by Lewis A. Stimson, New York, and George Ryerson Fowler, Brooklyn; Propriety of and Indications for Resection of the Appendix Vermiformis during the Quiescent Stage of Chronic Relapsing Appendicitis, by Joseph Price, Philadelphia, and Robert F. Weir, New York; Relation of the Physician and the Surgeon in the Care of Cases of Appendicitis, by Albert Vander Veer, Albany.

On Wednesday morning there will be a

discussion on Pelvic Inflammation in Women; its Pathology and its Palliative, Conservative and Radical Treatment, arranged as follows, Introduction, by Andrew F. Currier, New York; Pathology, by A. J. C. Skene, Brooklyn, and W. Gill Wylie, New York; Palliative Treatment, by C. C. Lee, New York; Conservative Treatment, by W. M. Polk, New York; Radical Treatment, by Joseph Price, Philadelphia, and L. S. McMurtry, Louisville, Ky.

These papers will be discussed by Dr. Thomas Addis Emmet, of New York, Dr. Franklin Townsend, of Albany, and others.

After this papers are announced on Treatment of Posterior Displacements by the Utero-Vaginal Ligature, by H. J. Boldt, New York; Minor Gynecological Surgery, by Maurice J. Lewi, Albany; Treatment of Injuries to the Floor of the Vagina, by Horace Tracy Hanks, New York; An Inquiry into our present knowledge of the Progress of Myomatous Tumors after (a) the use of the Electric Current, (b) Removal of Ovaries and Tubes, (c) The Old Method of Treatment by Rest, Intra-uterine Application and Ergot, by James F. W. Ross, Toronto; My Experience with the Surgical Treatment of Retroflexion and Prolapsus Uteri, by Paul F. Munde, New York; Surgical Treatment of Ectopic Gestation, by Charles A. L. Reed, Cincinnati, Ohio; Some of the Results of Defective Sanitary Arrangements in the Puerperal State, by James P. Boyd, Albany; Management of Tedious Labor, by Egbert H. Grandin, New York; Report of Four Cases of Cancer of the Clitoris where Clitoridectomy was performed, by Franklin Townsend, Jr., Albany; Emotional Element; the Puerperal Period, by Adam H. Wright, Toronto.

On Wednesday afternoon, there will be a discussion on Pulmonary Tuberculosis, as follows: History, by H. R. Hopkins, Buffalo; Etiology and Pathology, by Heneage Gibbes, Ann Arbor, Mich.; Diagnosis and Prognosis, by A. L. Loomis, New York; Manifestation in Upper Air Tract and Special Treatment thereof, by John O. Roe, Rochester; Treatment, including Propylaxis, as related to Climate, by Samuel B. Ward, Albany; Treatment as related to Therapeutics, including Koch's method, by E. L. Shurley, Detroit.

Papers will be read on Koch's Lymph and Tuberculosis, by A. Jacobi, New York; Therapeutical Notes on Acute Respiratory Diseases, by A. Jacobi, New York; Lobar Pneumonia, with the Production of Connective Tissue in the Air Spaces, by Francis Delafield, New York; The Treatment of Gall Stones, by William Wotkyns Seymour, Troy; Treatment of Itching, by Edward B. Bronson, New York; Croupous Rhinitis, by Frank H. Potter, Buffalo; Correction of Angular Deformities of the Nose by a Subcutaneous Operation, by John O. Roe, Rochester; Case of Pemphigus, by H. R. Hopkins, Buffalo; Treatment of Pigmentary and Vascular Nævi, by George Henry Fox, New York.

On Wednesday evening the Anniversary Address will be delivered by the President, and this will be followed by the Annual Dinner of the Society, at 9,30 o'clock.

On Thursday morning papers will be read on The Relation of Physicians to Boards of Health, by Lewis Balch, Albany; Necessity of an Amendment in the Laws Governing Medical Evidence in Malpractice Suits, by R. J. Wilding, Malone; Present Status of the proposed Law to regulate the Practice of Embalming human dead Bodies, by A. Walter Suiter, Herkimer; Unrestricted Evil of Prostitution, by Andrew F. Currier, New York; Case of Scarlet Fever with Vesicular Eruption, by F. C. Curtis, Albany; Intestinal Obstruction; Report of Cases, by J. H. Glass, Utica; Subject to be announced, by William S. Ely, Rochester; Subject to be announced, by Clarence C. Rice, New York.

Information in regard to the meeting may be obtained of the Secretary, Dr. Frederick C. Curtis, Albany, New York.

American Electro-therapeutic Association.

A convention of American physicians interested in electro-therapeutics has been called to meet at the Academy of Medicine, No. 17 West 43d St., New York, on January 22, 1891, at 11 A. M., for the purpose of organizing an American Electro-therapeutic Association. The call is signed by Drs. G. Betton Massey, Augustin H. Goelet and Horatio R. Bigelow.

NEWS.

—Dr. Myron Knowlton, of Rochester, N. Y., died at the age of 84 years, December 30, 1890.

—Dr. B. S. Warren, aged 65, a promi-

nent physician of Concord, N. H., dropped dead of heart disease, January 1, 1891.

—Dr. Wellington V. Walker, formerly on the staff of the City Hospital of Louisville, Ky., died suddenly at Mexico, Mo., in December.

—Dr. F. W. Dancy, a prominent physician, and President of the State Board of Health of Mississippi, died at his home in Holly Springs, Miss., on November 8, 1890.

—Dr. Frederick T. Outley, a rising young physician of St. Louis, and who spent some years in the service of the city Health Department in the capacity of quarantine physician, died December 28, 1890.

—Dr. Anson L. Hobart, for 32 years a practicing physician in Worcester, Mass., died December 31, 1890, 76 years old. He was a native of Columbia, N. H., and a graduate of Williams College, class of 1836.

—Dr. Elisha Sterling, of Cleveland, died in that city December 29, 1890, after a short illness. He was born at Palisbury, Conn., in 1825, and was brought when a child to Cleveland, when it was a backwoods settlement. He was an ardent student of fish culture, as well as an able surgeon.

—The hospital in Brooklyn conducted by Dr. Mary Dixon-Jones and her son—who were not long ago held for manslaughter—has been criticised again because of alleged false statements to the Brooklyn Board of Estimate, to which it was making application for an appropriation from public funds.

—Dr. McDaniel Purcell died recently in this city in his thirty-second year. He was graduated from the medical department of the University of Pennsylvania about eight years ago. He had been in ill health for several years, but his last illness lasted but two weeks. He was a native of Richmond, Va., and his body was taken there for burial.

—The Imperial authorities of Russia have invited Sir Joseph Lister, Dr. Koch and Professor Pasteur to a conference, with a view to founding and establishing a bacteriological institute at St. Petersburg. Sir Joseph Lister was unable to accept the invitation, and Mr. Watson Cheyne recently left London to take his place as the English representative.

—Passed Assistant Surgeon Kinyoun, of the Marine Hospital service, who was recently sent by the Marine Hospital Bureau to Berlin to enter Koch's laboratory, reported by cable, on January 7, his arrival and asked for authority to purchase the necessary apparatus. The authority was immediately granted. Dr. Kinyoun will remain in the laboratory three months.

—Eight patients are being treated in the New York Post-Graduate Hospital by Koch's lymph. Three of them are cases of lupus; four are cases of phthisis pulmonaris, and one laryngeal tuberculosis. The inoculations are in charge of Dr. W. C. Bailey, who was for a long time a student in Koch's laboratory, assisted by the Director of the Laboratory, Dr. J. H. Linsley.

—The comparatively rare accident of fracture of a rib by muscular action took place in Philadelphia, January 7, 1891. A woman, fifty-nine years old, had gone into a shoe store to purchase a pair of shoes. After trying them on she stooped over to button them, when she heard something snap, and at the same time experienced a stinging sensation in her side. As the pain continued to grow greater she went to the Episcopal Hospital, where Dr. Boger, upon examination, found that one of her ribs was broken.

—Dr. Gideon B. Perry, one of the oldest practicing physicians in Brooklyn, died suddenly December 30, 1890, at his residence, 627 Bedford avenue. He was born at Hopkinton, R. I., in 1826. He first studied medicine under his father, who was a medical practitioner in the town in question. Later he assisted Dr. Alonzo Clark, of Pittsfield, Mass. He next entered the medical department at the University of the City of New York, graduating therefrom in 1851. In the same year he established himself in practice in Brooklyn, and from that time up to the moment of his death had pursued a professional career of singular activity and success.

—The first of the proposed "Leprosoria" in the Baltic provinces will, it is hoped, be ready for occupation in the spring. A valuable piece of land having been presented for the purpose by the landowners at Nennal, a village seventy versts distant from Dorpat, it is proposed to locate upon this forty or fifty lepers who are still able to work. A small branch establishment, or hospital, for severe cases—especially such as require operative measures—is to be established in the immediate vicinity of Dorpat. This hospital will contain ten or fifteen beds. It will be employed also as an observation station, where patients may be kept before being sent on to Nennal.

"Familiar in millions of mouths as any household word."
—*The Times.*

Apollinaris

"THE QUEEN OF TABLE WATERS."

"*In* 1873 *the number of bottles filled and exported was a little under* 2,000,000. *Last year the number was nearly* 16,000,000.

"*Filling went on at the rate of* 90,000 *a day.*

"*These figures are gigantic.*"

THE TIMES, LONDON, 20th Sept., 1890.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

Constipation.

Pavara Pills are prepared especially for the treatment of Constipation. They are tasteless, harmless, and *produce natural movements of the bowels, without pain, nausea, or any inconvenience whatever.*

Physicians are requested to test these pills in those cases which they think to be incurable, also, in cases of **constipation during pregnancy.** Thousands of physicians now use and prescribe them.

Physicians will see by the **formula** (on the outside label) that each medicinal ingredient is **absolutely harmless.**

Prices: small bottle (25 pills), 25c.; large, (150 pills), $1.00. Liberal discount to physicians.

A large bottle will be mailed to **any physician,** for trial, on receipt of 25 cents in postage stamps.

Prepared by C. L. TOPLIFF, New York. Depot, 115 Fulton Street.

Please mention this Journal.

FRAUD.

Unscrupulous parties are selling an inferior Wine, calling it Royal Tokay, thus profiting by the numberless Medical Editorials written about our genuine product. The Wine cannot be used as a substitute for ours, and many physicians have unjustly blamed us for damage done, imagining they were securing our Wine, which they had already tested with complete satisfaction. Your patients will not secure the Wine you prescribe unless you specify CALVICO TOKAY, by which name it will hereafter be known.

A CASE WITH A LESSON IN IT.

We have frequently referred to the necessity of keeping the pregnant woman supplied with those chemical substances which she must give to the child in the formation of its little frame, and the dire effects which may result from a deficiency of those substances. The headaches, neuralgias, spinal tenderness, and some of the many disorders of digestion, and even mental failure, may be all prevented or relieved by supplying to the mother the chemical food her system demands.

We have noticed a few cases where the most serious results have occurred to the mother by such a deficiency, one of which is well worth relating. Mrs. M., aged 30, pregnant with her third child, suffered from the second to the fifth month of her pregnant term with gradually failing strength and health, and nervous irritability. She was very restless nights for three or four days, the peculiar restlessness of complete nervous exhaustion, and was irrational for more than a week.

At this time I advised that she have a teaspoonful of Murdock's Liquid Food every hour in milk, and a little wine every four hours. The third night she had fifteen drops of hydrobromic acid dil. every three or four hours, which was continued for a week. The liquid food after a week every two hours, and all other medicines were discontinued. Her bowels were moved with a mild laxative at first, and afterward became regular. Her tongue cleaned quickly and her skin assumed a more natural appearance.

At this writing, less than three weeks from our first visit, the patient is able to sit up an hour at a time, is quite rational and cheerful, has a good appetite, the bowels are quite regular, there is no headache, and but little spinal tenderness. She sleeps reasonably well if fed frequently. She is allowed to suit her taste in her diet. The child is quite active, and the mother is progressing so nicely that it is hoped that she will pass safely through her confinement, which is nearly at hand. She will be kept on the liquid food and the phosphates until her confinement after which, the condition will suggest the treatment. This is the most marked case of a starved nervous system we have ever seen, and the benefit derived from the treatment proves the theory as to the cause of the trouble.

Apropos with the above, comes the question of the selection of nutritious foods for those many cases which demand strong and immediate nourishment. The food used in the above case has produced marvelous results for us in some of those extreme cases in which we have used it.

In one case of nervous exhaustion the insomnia was absolutely painful. When the exhaustion forced the patient to sleep there was an immediate sense of falling or approaching death, or there were hallucinations which were appalling, rendering the nights unbearable. One teaspoonful of Murdock's Liquid Food so nourished the system the first night it was given that the patient sank into a quiet, refreshing sleep which lasted, with a single awakening, until morning, and the improvement the patient obtained was most striking.

One case of mitral regurgitation with leucocythemia and nervous exhaustion improved more rapidly on this food than on all other measures combined. In cases of nervous exhaustion and brain tire, its effects are most marked, as we have experienced many times in the past five years in the frequent personal use of the agent. It contains the principles of pure, healthy blood and nerve tissue ready for immediate assimilation. Fourteen per cent. of the entire quantity is uncoagulated albumen, as we have demonstrated by actual analysis.

We have tided babies over critical periods often with a few drops in its usual diet. We have given it to dipsomaniacs with or without non-alcoholic stimulants with superb results. The sole objection our patients have to it is its odor. Its taste is not disagreeable; it has the odor and appearance of blood. All objections are soon forgotten, however, in the results of its action upon the nutrition of the system, and the patient soon learns to like it, and often craves for it, drinking it from the bottle or a glass readily, like any beverage. It ought to be the food par-excellence for rapid appropriation in all conditions of exhaustion.

P. S.—Phosphates act well with the Liquid Food.

Editorial of the Chicago *Medical Times*, June, 1890.

FOR THE CURE OF

NERVOUS HEADACHES

SEDATIVE EFFERVESCENT

BROMO (WARNER & CO.) SODA

℞ Caffein 1 grain, Brom. Soda 30 grains in each heaping teaspoonful.

Useful in Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness and Epilepsy.

Dose and Composition.—A heaping teaspoonful, containing Bromo-Soda 30 grs., and Caffein 1 gr., in half a glass of water, to be repeated once after an interval of thirty minutes if necessary.

EFFERVESCENT ANODYNE

BROMO (WARNER & CO.) POTASH

℞ Caffein 1 grain, Bromide Potash 20 grains in each heaping teaspoonful.

Useful in Nervous Headache, Sleeplessness, Excessive Study, Migraine, Nervous Debility, Mania, as a Remedy in Seasickness and Epilepsy.

☞ **Physicians** desiring the Potash Salt can obtain the same by ordering or prescribing **Bromo-Potash (Warner & Co.)**, the composition of which is: Brom. Potash 20 grs., Caffein 1 gr.

☞ The composition of the above effervescent salts is such as physicians can use with confidence, and you will please specify **Bromo-Soda** or **Bromo-Potash, Warner & Co.**, when ordering or prescribing to avoid the substitution of other "Bromos." Prepared only by

WILLIAM R. WARNER & CO.,

1228 MARKET STREET, PHILADELPHIA. 18 LIBERTY STREET, NEW YORK.

FRENCH, CAVE & CO.

(SUCCESSORS TO FRENCH, RICHARDS & CO.),

PHILADELPHIA,

WILL continue the manufacture of the Fine Pharmaceutical Products made by the late firm at the present laboratory, **16 and 18 North Tenth Street, Philadelphia.**

Physicians who have prescribed these preparations can rest assured that the high standard of quality which has made for these products a reputation for consistent strength and purity will be strictly maintained in the future, and the physician can always prescribe our preparations and depend on uniform results

To those physicians who have not yet prescribed our products, we request them to send to us their address and we will forward by **EXPRESS, PREPAID,** a line of samples free for trial.

Physicians' Price-List and Formulary sent by mail on application.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

To avoid the evil effects of Tea and Coffee, use constantly VAN HOUTEN'S COCOA, which is a STRENGTHENER OF THE NERVES and a refreshing and nourishing beverage.

One trial of VAN HOUTEN'S COCOA will convince every one of its *great superiority in strength, flavor, and economy.*

PURE, SOLUBLE, Delicious

THE STANDARD COCOA OF THE WORLD. A SUBSTITUTE FOR TEA & COFFEE. Easily Digested—Made Instantly.

HIGHEST AWARDS AT PRINCIPAL EXHIBITIONS. The Original—Take no other.

SULFONAL-BAYER.

A CORRECT METHOD OF ADMINISTRATION, ESSENTIAL TO OBTAINING ITS HYPNOTIC EFFECT.

Inquiries have been made of us from time to time as to the best method of administering Sulfonal-Bayer. These inquiries indicate that various methods of administration have been employed, and this, without doubt, accounts for those cases where the results obtained were not wholly satisfactory. We call special attention to the following:

"*Clinically observed, we recognize in Sulfonal a mild calmative,* a slowly but progressively active hypnotic. *It has no other action, and its operation is attended by no complications, near or remote. It is, therefore, a pure hypnotic.*"

"*The essential conditions of success in the exhibition of Sulfonal depend on first, the* time *when the remedy should be administered; second, the* method *of administration; third, the* dose."

"*It is a fact, perhaps wholly unprecedented in what we observe of other neurotic materials, that Sulfonal demands from two hours to one hour for its physiological incubation; often quite two hours elapse between ingestion and the first accession of sensible medicinal energy. With the untried subject it is wise to stipulate for two hours.*"—[Extracts from articles by PROF. H. M. FIELD, *New England Medical Monthly; Therapeutic Gazette.*]

According to the experience of Prof. A. Kast, of Freiburg University, Sulfonal-Bayer should be administered in a plate of soup, a cup of hot *tea, milk or broth, at least two hours before retiring, or with the last meal early in the evening, between 7 and 8 P. M., at which time the stomach contains considerable amount of muriatic acid, mineral salts and peptones, and the most favorable conditions for the absorption are satisfied.*

Sulfonal has just been incorporated into the Addendum to the British Pharmacopœia.

Sulfonal-Bayer, prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, is supplied by us in ounces and in the form of Tablets of 5, 10 and 15 grains, put up in bottles of 10 and 100 tablets each.

We also offer Sulfonal-Bayer in the form of our soluble pills, containing 5 grains each.

ARISTOL.

In order to secure the desired effects of Aristol, it is important that the physician be certain *that the article used bears the guarantee furnished by the continuous scientific control and the name of the manufacturers, the "Farbenfabriken, vormals Friedr. Bayer & Co., in Elberfeld." This firm are the* only *manufacturers of this article, and the word "Aristol" is their registered property.*

The preparation of Aristol, theoretically simple, involves the greatest care and experience.

Aristol, a combination of iodine and thymol, manufactured by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, Germany, is a valuable, inodorous, and non-toxic antiseptic remedy, superior to iodoform, iodole, and sozo-iodole.

The general specific action of Aristol is similar to that of iodoform, iodol, and the sozo-iodol compounds, but in addition it has the valuable property of forming an absolutely unirritant covering over the surfaces on which it is placed, under which the processes of granulation and cicatrization proceed with extraordinary rapidity.

Aristol is indicated in Mycosis, Lupis, Psoriasis, Syphilitic diseases generally, etc., etc.

Descriptive pamphlet mailed on application.

PHENACETINE-BAYER.

Antineuralgic-Antipyretic.

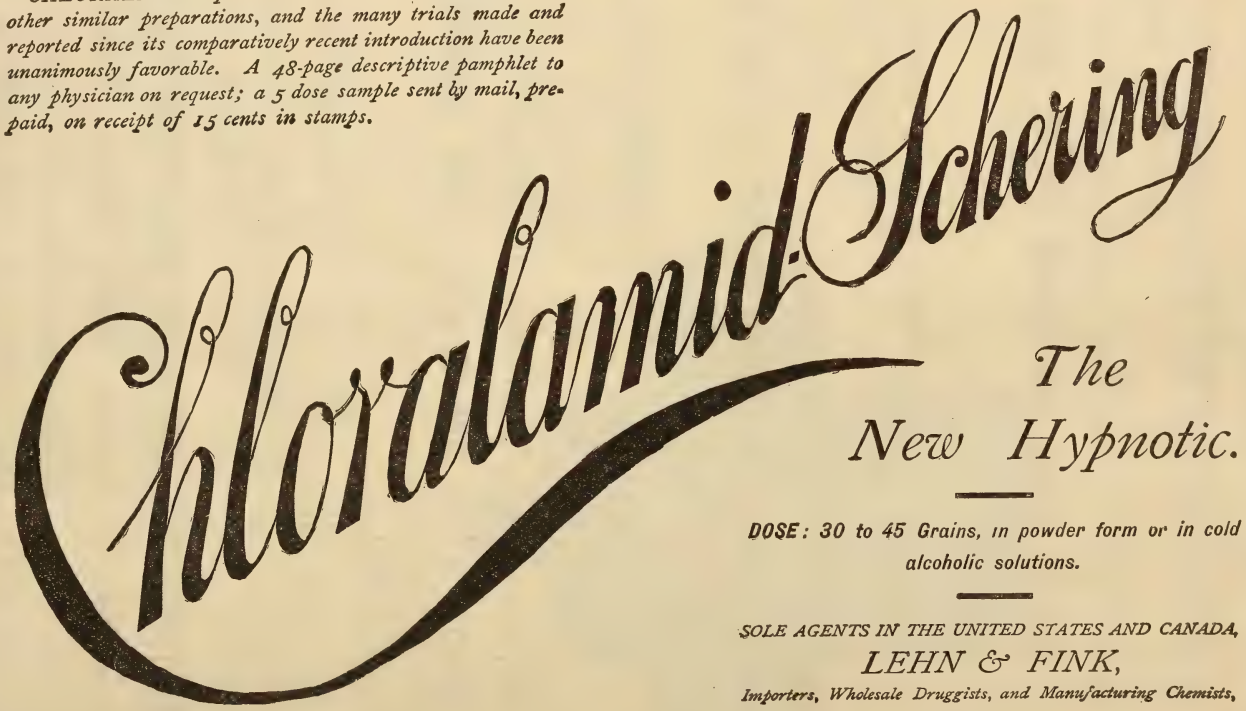
Much valuable testimony regarding Phenacetine, furnished by the medical profession of other countries, as well as our own, has, from time to time, been collated by us, and the same has been put before American practitioners.

The scope of Phenacetine having widened, we have brought together in pamphlet form, classified in respect to diseases indicated, the results of the latest experience as reported chiefly by American physicians.

This pamphlet mailed to applicants.

W. H. Schieffelin & Co.,
170 & 172 William Street,
NEW YORK.

CHLORALAMID possesses undoubted advantages over other similar preparations, and the many trials made and reported since its comparatively recent introduction have been unanimously favorable. A 48-page descriptive pamphlet to any physician on request; a 5 dose sample sent by mail, prepaid, on receipt of 15 cents in stamps.



The New Hypnotic.

DOSE: 30 to 45 Grains, in powder form or in cold alcoholic solutions.

A BRIEF SUMMARY

OF

HYPODERMIC MEDICATION.

will be sent, with our compliments, when application is made and the name of this journal is mentioned. It quotes Profs. Dujardin-Beaumetz, Bartholow, Anstie, Erb, Echeverria, Mays and others. It contains important and the most recent suggestions on the technique of hypodermic medication, and gives the composition, properties, doses, etc., of our

SOLUBLE HYPODERMIC TABLETS, S. & D.'s.

which are quickly and perfectly soluble in cold or warm water, combining accuracy of dose with perfect preservation of the active ingredient, and the base of which is perfectly harmless and unobjectionable. They will cause no abscesses and will not become insoluble by age. They may also be administered by the mouth, and are

ALWAYS READY FOR INSTANT USE.

We respectfully solicit a trial of these tablets, and will mail samples of them free to readers of this journal.

That the several objections to hypodermic medication might be obviated, we have had manufactured expressly for us a line of

HYPODERMIC SYRINGES, S. & D.'s,

which have all the latest improvements, are most accurately made of the best materials and so constructed as to allow the

MAKING OF A SOLUTION IN THE SYRINGE.

They are sent to any address at the following prices:

Syringe, in leathered-covered case, two tubes of tablets . . . . . net, $2.50
" " metal case, latest improved style, two tubes of tablets . . . . . " 2.50
" " " " four tubes of tablets . . . . . " 3.50
" " flexible leather case, as shown by cut 3.50

ESTABLISHED 1860. 3 BALTIMORE, MD.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron**, is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

Paris—CLIN & CO.—Paris

AND BY ALL DRUGGISTS.

CAPSULES MATHEY-CAYLUS

WITH THIN ENVELOPE OF GLUTEN.

CONTAINING COPAIBA AND ESSENCE OF SANTAL; COPAIBA, CUBEBS, AND THE ESSENCE OF SANTAL; COPAIBA, IRON, AND THE ESSENCE OF SANTAL.

"**The Mathey-Caylus Capsules,** of the *Essence of* "*Santal*, associated with the Balsams, possess an incontesta- "ble efficaciousness, and are employed with the greatest "success for the rapid cure of old or recent *Discharges*, "*Gonorrhœa, Blenorrhœa, Leucorrhœa, Cystitis of the Neck*, "*Urethritis, Catarrh*, and other *diseases of the bladder*, together "with all affections of the *Urinary Passages*."

"Thanks to their thin envelope of *Gluten*, which is essen- "tially assimilable, the *Mathey-Caylus Capsules* are digested "by the most delicate persons, and never weary the stomach."

—*Gazette des Hopitaux de Paris.*

CLIN & CO., Paris,

AND OF ALL DRUGGISTS.

NEURALGIAS

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con-* "*gestive neuralgias*, and *painful and inflammatory Rheumatismal* "*affections*."

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious Elixir, **QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the three Cinchonas' barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

E. FOUGERA & CO., New York,

Sole Agents for the United States for the above Preparations.

TERTIARY SYPHILIS.

"Your preparation, **IODIA**, is an excellent alterative, and is the most agreeable of any preparation of Iod. Potas., as it does not cause the cramps in stomach, which are often intolerable.

"I have employed **IODIA** in two cases of Tertiary Syphilis, in which, after five weeks' treatment, the manifestations disappeared.

"In a case of Syphiltic Eczema it was also successful. —Dr. Sam Petiteau, Garches, France, Nov. 10, 1890.

WHAT IS THOUGHT OF THEM!

(BOOKS FOR SUBSCRIBERS TO REPORTER.)

☞See adv. page viii.

HEATH'S DICTIONARY OF PRACTICAL SURGERY.

C. B. Porter, M. D., Boston, Mass., says; "A most excellent book for the library of the surgeon, and especially for the country practitioner; as a book of reference it is so concise and at the same time so complete."

N. Senn, M. D., College of Physicians and Surgeons, Milwaukee, says; "As a means of ready reference for the student and busy practitioner this book stands unexcelled."

Prof. E. H. Gregory, St. Louis Medical College, St. Louis, says: "I have examined the book, and find it a most valuable addition to my library. I am sure it will meet the favor of the surgical profession."

LEIDY'S HUMAN ANATOMY.

The Lancet-Clinic, Cincinnati, O., says: "Professor Leidy again presents to medical practitioners and students a treatise on human anatomy that at once commands the attention and admiration of all who are at all familiar with the subject. Most of the plates are original, and in common with the text are very beautiful to behold. The work is a complete illustration of the method of teaching anatomy adopted by a leading scientist, and one of America's best known professors of anatomy. This is one of the books that should be in the library of every practitioner of medicine and surgery."

The Medical Advance, Ann Arbor, Mich., says: "The student can master and retain a practical knowledge of anatomy in a shorter time and with less hard work from this text-book than from any other work extant, and it has been our privilege to teach anatomy for several years."

BYFORD'S DISEASES OF WOMEN.

The Boston Medical and Surgical Journal says: "It is a satisfaction to observe the discussion of certain topics which are often neglected by writers, notably of the sympathetic symptoms of organs apparently disconnected with the uterus, for which he will receive the thanks of the younger members of the profession. Another topic very widely treated is that of Constipation in its relation to uterine diseases. All the other topics which should have a place in a work of this kind have been fully and properly treated."

The Cincinnati Lancet-Clinic says: "The book is eminently practical and instructive. Its suggestions for treatment are well up with the times, mostly judicious, conservative, and valuable, and the whole amply repays for thorough perusal."

The St. Louis Courier of Medicine says: "The work of a representative Western practitioner and professor, and is a thoroughly practical work."

The Virginia Medical Monthly says: "We take pleasure in recommending it to every student and physician desirous of obtaining a standard work on Gynæcology."

The Chicago Medical Journal and Examiner says: "The chapter on puberty should be carefully studied by every physician, teacher, and mother in the land. . . . Its style is clear, but concise, and always practical, and shows the author to be, as we all know, an experienced teacher. The work as a whole is most valuable, both to the student and practitioner."

Gaillard's Medical Journal says: "It is replete with good judgment, broad and practical views. . . . The illustrations are excellent."

FOWLER'S DICTIONARY OF PRACTICAL MEDICINE.

The Medical News says: "For those who do not wish to purchase the much larger book of Quain, or who wish comparatively recent information concerning medical subjects in a somewhat narrow space, the book will certainly prove of value, and we heartily recommend it as one which will give a full return for the money invested in the purchase."

The London Lancet says: "What the writers know they tell simply and plainly, and generally manage to put it in a short compass, and, what is more, the treatment that is recommended is clearly and sufficientiy set forth. . . . We can heartily congratulate the editor and his colleagues on having admirably fulfilled their purpose, viz., to produce a first-rate dictionary of medicine, at once scientific and practical, which well deserve the success we have no doubt it will meet with."

JACOBSON'S OPERATIONS OF SURGERY.

The Medical and Surgical Reporter says: "This handsome book is one of the most admirable works on operative surgery which we have seen for a long time. The author has brought to its preparation a large observation and experience, and a very thorough acquaintance with the methods of other surgeons. His book is comprehensive and his directions are clear and reliable. It is gratifying to an American reader to find that full justice is done to the work of American surgeons by Mr. Jacobson, and that his book bears no marks of the distance which stretches between his land and ours. This is as it should be, and is no less an element in the excellence of the technical worth of his book than it is an evidence of the cosmopolitan character of good scientific work."

CAZEAUX & TARNIER'S MIDWIFERY. With Appendix by MUNDÉ.

The Memphis Medical Monthly says: "Cazeaux's Obstetrics was authority during our student life, and has been generally recognized as authority from the publication of the first edition to the present. We cannot do more than to fully endorse the following from the pen of T. Gallard Thomas, M. D; 'I have examined the last edition of Cazeaux & Tarnier's Theory and Practice of Obstetrics, and pronounce it practical, and just what is needed by every practitioner. I highly recommend the work. This work should be prominent in every library.'"

Dr. Wm. L. Lusk says: "Cazeaux's Midwifery will always remain an inexhaustible mine of information, and I rejoice to see it once more accessible to the profession in a new and attractive dress."

Dr. Wm. Goodell says: "I deem Cazeaux & Tarnier's Obstetrics the best yet published."

The Denver Medical Times says; "It is needless to say anything in praise of this work. Cazeaux's Obstetrics is a classical work, and Tarnier is one of the best known French writers on Obstetrics. The whole has been brought up to date by the appendix of Prof. Mundé, and altogether it makes a very complete and practical treatise on the subject, unsurpassed if not unequalled by any work with which we are acquainted. Especially valuable are the signs of delivery in the dead body and of live and still-births. The chapter on antisepsis and on puerperal septicemia are also worthy of mention."

THOMAS'S MEDICAL DICTIONARY.

Prof. A. F. Patton, College of Physicians and Surgeons, Boston, Mass., says: "It is just the book for a medical or any other student, and it should be in the office of every physician. This dictionary supplies a place that has never been filled. I have looked it through and find all the new words that I have sought."

The St. Joseph Medical Herald says: "No better testimonial to the value of the work can be given than the following from Dr. J. Gibbon Hunt, the distinguished microscopist: 'To me the work is invaluable. I am astonished at its fullness of all recent words which the modern advance of medical science has introduced. Of course, I cannot conceive the learning and great labor which could edit such a complete, thorough, and admirable volume.' We can add nothing further save that the book should be in the hands of every physician and every student in the land."

ABOUT GAS TREATMENT.

We make and sell oxygen and nitrogen monoxide for therapeutic use, and we guarantee them pure. They are put up in compact form. (A cylinder containing 100 gallons of nitrogen monoxide or 40 gallons of oxygen measures 12 inches in length, has a diameter of 3½ inches, and weighs 10½ lbs. A cylinder containing 450 gallons of nitrogen monoxide or 100 gallons of oxygen measures 25 inches in length, has a diameter of 4½ inches, and weighs 34 lbs.)

INSOMNIA. Dr. Allan McLane Hamilton states that nitrogen monoxide, N_2O (nitrous oxide of the old nomenclature) has no equal in the treatment of this difficulty.

MELANCHOLIA. A short course of nitrogen monoxide is said to change the face of nature for such patients.

ANÆMIA. Where iron is not tolerated or proves inefficient, the addition of oxygen or a combination of oxygen and nitrogen monoxide has proven very beneficial.

For those who should, but cannot, go from home for rest or a change of air, or for those who, from any cause fail to get air enough into their lungs, the inhalation of one or other of these gases, or both in combination, promises great benefit. The testimony is that in cases of

ASTHMA, more than fifty per cent. of the cases yield to oxygen treatment, others are very greatly relieved, and a very small per cent. are not improved.

INDIGESTION and CONSTIPATION are said to be greatly relieved and very often conquered by continued treatment.

A highly esteemed New York physician has used more than twenty thousand gallons of nitrogen monoxide in his private practice. The letters received from his patients, largely from those who were afflicted with nervous disorders, are enthusiastic in their testimony as to the benefit received.

Regular practitioners who are using gas treatment testify that when *pure* oxygen and *pure* nitrogen monoxide, or a mixture of these, is used, no therapeutic agents are more uniformly successful when intelligently prescribed.

For descriptive circulars, and term for gas outfits, address

1260 and 1262 Broadway (cor. 32d St.), New York, N. Y. 444 Fulton St., Brooklyn, N. Y.

NERVES.

Suppose we find the patient a little giddy upon rising in the morning. This means that the nerves do not have perfect control of the muscular system. As a test for this, direct the patient to stand with his feet close together, shut his eyes, and if the tendency is to reel, it is another evidence of lowered nerve tone. Or, stand with the arms extended, shut the eyes, and then try to bring the tips of his forefingers together in front of him. If they pass by or meet imperfectly, it shows the same thing.

Or, the person may not be able to think as quickly as he should. To test this, ask the patient three simple questions in rapid succession, as, Where were you just before you came into this room? What were you doing? How long did you remain? The rapidity with which the answers are given indicate the rapidity of brain action.

All these things show that it is of the utmost importance that the nervous system should be kept in tone. Otherwise, every part of the body languishes.

This condition indicates the use of Celerina (Rio) in teaspoonful doses four times a day, *to increase the nerve capital of your patient.*

LIQUOR SANTAL FLAV.

CUM

BUCHU ET CUBEBA.

(ORIGINAL FORMULA.)

This elegant preparation has been very successfully used in the treatment of long-standing Gonorrhœa and chronic Gleet.

If given in the early stages of Gonorrhœa, it will usually arrest the progress of the disease.

It is especially effective in all inflammations of genito-urinary mucous membranes.

It is perfectly miscible in water. Dose, f℥i to f℥ij, three times a day in water or milk. When prescribing, please specify Liq. Santal Flav. cum Buchu et Cubeba (Ogden's).

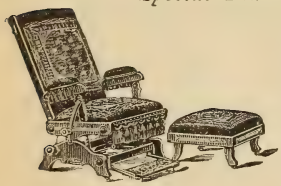
THE RIP VAN WINKLE RECLINING ROCKER

OFFICE AND GYNÆCOLOGICAL CHAIR COMBINED.

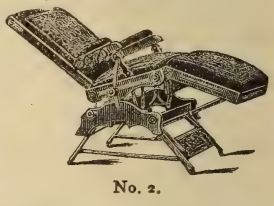
Special Inducements and Extra Discount Given to Physicians.



No. 1.

It is the most wonderful Chair in the world. You can sit in the Chair with your feet on the foot-rest and rock yourself, and it is impossible for a beholder to tell what makes the Chair rock. It is the finest invalid's Chair in the world.

As an **Invalid's Chair**, a person can recline the back by quarter-inches until he lies straight or horizontally, and without taking his weight from the back of the chair in the least, and CAN ROCK AS WELL LYING DOWN AS SITTING UP. Upholstered in Plush, Leather or Wilton Rugs. This Chair has over 200 changes of position, and sells for $25.00.

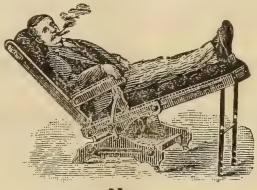


No. 2.

This Chair can be converted from a splendid Office Chair (see cuts Nos. 1 and 3) into one of the most complete Gynæcological Chairs in a half minnte, (see cuts 2, 4, and 5).

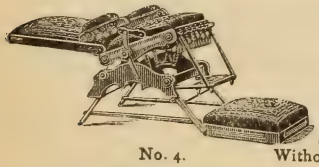
As a Gynæcological Chair it will take all the positions of the high-priced chairs costing two and three times what this one does.

The Rip Van Winkle Chair has over 200 changes of position. Every chair fully warranted.



No. 3.

This Chair is sold with or without the Gynæcological attachment, as desired. It is *unquestionably* the most complete and comfortable Reclining or Lounging Chair ever made. I make a special price to physicians, and also give them a handsome commission on all orders I receive through them for Chairs for their patients. No Chair in the world is so well adapted to ladies suffering from female weakness, and the commission I give on your orders will soon pay for your own Chair.



No. 4.

The Chair makes 5 pieces of Furniture.

I have attachments by which it can be converted into an Invalid's Rolling Chair in one minute. Parties can get these attachments from factory at any time. Send for full particulars, price-list, and illustrated catalogue showing the principal positions and changes. The Catalogue contains the "Legend of Rip Van Winkle."

Without the Gynæcological Attachment these Chairs

No. 5.

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

Physical Exhaustion

HORSFORD'S ACID PHOSPHATE.

It is a well-known physiological fact that the phosphates are involved in all waste and repair, and are consumed with every effort. The quantity secreted by the kidneys is increased by labor of the muscles.

In the healthy organization the phosphate of lime exists in the muscles and bones. This phosphate is supplied by this preparation in such form as to be readily assimilated.

Dr. J. P. COWLES, Camden, Me., says: "I have used it in cases of physical debility arising from exhaustive habits or labors, with beneficial results."

Send for descriptive circular. Physicians who wish to test it will be furnished a bottle on application, without expense, except express charges.

Prepared under the direction of Prof. E. N. HORSFORD, by the

Rumford Chemical Works, Providence, R. I.

Beware of Substitutes and Imitations.

CAUTION:—Be sure the word "Horsford's" is printed on the label. All others are spurious. Never sold in bulk.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{30}$ gr.), Atropiæ Sulph. ($\frac{1}{300}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{10}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

Clinical Lecture.

RHEUMATOID ARTHRITIS.—SYPHILITIC HEADACHE.—MALARIAL CACHEXIA.—DIVISIONS OF THE ANEMIAS.

BY JOHN H. MUSSER, M. D.,

ASSISTANT PROFESSOR OF CLINICAL MEDICINE, UNIVERSITY OF PENNSYLVANIA; VISITING PHYSICIAN TO THE PHILADELPHIA HOSPITAL.

Rheumatoid Arthritis.

Gentlemen: At our last meeting we studied the symptoms, course and treatment of syphilitic, gonorrhœal and simple rheumatism; to-day we will take up a disease which occupies an uncertain position in the nosology of this broad subject. The exact relationship existing between rheumatism and rheumatoid arthritis has not been determined; yet there can be no doubt that it is definite and certain. Rheumatoid arthritis is a disease associated with grave anatomical changes, which appears in gouty subjects, with other affections known to be rheumatic, frequently mingled with other well recognized gouty or rheumatic symptoms. It is also occasionally associated with lesions common in other rheumatic affections, chronic kidney trouble, endocardial inflammations, etc. In syphilitic rheumatism the enlarged lymph glands facilitate diagnosis; not so much the glands in the groin—which are apt to enlarge on any adjacent irritation—as the post-cervical or epitrochlear glands. If these are swollen, it is an important aid to diagnosis. In gonorrhœal rheumatism there is an effusion into the joint of a thick, cloudy, serous exudation, which is not pus, nor yet serum. In rhematoid arthritis every component part of the articulation shows symptoms of chronic inflammatory change. There is the curious contraction, the character of which I am unable to describe; the position and shapes of the joints are altered; new growths of bone appear around the heads of the small bones—for the smaller joints are the ones generally affected; the articular cartilage is absorbed; masses of hypertrophied cartilage appear in the synovial processes; the articular cartilages relax, and displacements and sub-luxations of the unshapely bones occur. Crepitus can be detected, until the process is so far advanced that immobility exists.

In the case before us, which was sent to us as a true example of this disease, there is no bony enlargement, no crepitus on movement, no sub-luxations, no disorganization of the heads of the bones. It is rather a case of chronic rheumatism with contractures than a good specimen of rheumatoid arthritis.

Syphilitic Headache.

The next patient is a man, aged 30, whose habits are fair; he is a tobacco user and a moderate beer drinker; he has no especial family history. He is said to have had malaria in Italy thirteen years ago. On the fifth of August he noticed a chancre; this was followed by no secondary symptoms. On the morning of September 17 he awakened with pain in the leg. This pain spread to the lumbar region, and subsequently to the occipital region. It was throbbing in nature, worse on movement and at night. On admission he had no fever, but on having his temperature taken for the past two days, we found that it ranged from 100° to 100$\frac{4}{5}$°. All this time, despite the use of anodyne and other remedial measures, his condition grew worse. He was unable to sleep and his general health was beginning to suffer. The possibility of the existence of headache due to disease in other organs—the so-called secondary headaches—led to a careful study of this man's condition. There was present no gastric or intestinal disturbance which

would account for the symptom. His heart, liver and kidneys were in good order. The possibility of toxic headache being the real condition then suggested itself. Malaria, lead-poisoning, rheumatism, syphilis, the early stages of the fevers—especially typhoid—are all frequent sources of this troublesome symptom. There is an old history of malaria, thirteen years ago; there have certainly been rheumatic pains throughout the body; and he has had the primary lesion of syphilis. Rest in bed, with warmth and diet, have brought relief from the pains in the body of which he complained on his admission. They were undoubtedly distinct from his headache. The pain in his head is localized in the occipital region; it is acute, and the spot is tender to the touch. There is no trace of any malarial poisoning; the spleen is not enlarged; there is no cachexia or pigmentation; the blood is in good condition; the man has been in the hospital too long to think of the existence of any of the specific fevers; and no trace of lead-poisoning exists. In obscure cases there can be found frequently traces of trouble which point towards rheumatism; the family history, the occupation, the large quantity of uric-acid crystals in the deposits, high color of the urine, or high specific gravity, are all suggestive of rheumatic involvement.

From the study of the case, we determined that anti-syphilitic remedies should be tried. This early in the course of syphilis, the use of mercurials with the iodide of potassium is indicated. This treatment has been tried for a few days with the result that the man has had two fair nights, when he experienced sufficient relief from his pain to obtain considerable sleep.

Malarial Cachexia.

The next patient exhibits such a degree of pallor that we can at once decide that some grave change must have taken place in the economy. It is difficult sometimes to distinguish jaundice from anemia, which tends towards sallowness. The patient, a man aged 52, was born in North Carolina, and was a resident of that State until within a few months. He is a laborer, one of that class which fills this hospital almost exclusively. He has used alcohol moderately, tobacco not at all; which is somewhat remarkable for a native of a tobacco-growing State. He confesses to no venereal diseases. His family history is exceptionally good; no history of hereditary disease exists. Of course he has been for years a constant sufferer from malaria. He has lived for many years in the swamps of North Carolina, where this disease is indigenous. Although living among the so-called "dirt-eaters"—people of the region who have that unpleasant symptom "pica," or a gnawing desire for unnatural and unsuitable food—he is not one of them. In July of this year he suffered with chills every day; at this time he was taking quinine just as we would take our daily bread. Under this extreme dosing the chills appeared only every third day. Suddenly, four weeks ago, these chills began again every day, each day one-half hour later. On admission the man was weak, exhausted and breathless. Early the next morning after admission he had a chill, when his temperature went up to 104°; later descending to normal. The next two days he had no chill; although on the second day his temperature ran up to 103°, followed by a profuse perspiration. His color is striking; it is a lemon-yellow, with the sclerotic and mucous membrane of the conjunctivæ blanched. All the evidences of anemia exist; there are murmurs in the vessels and heart, indicative of the poverty of the blood.

In this case there have been found none of the characteristics of malarial poisoning; the pigment, floating free or confined in the corpuscles, is wanting. There are, however, organic changes which show the influence of long-continued malarial action. The spleen is greatly enlarged. Normally it extends from the eighth to the tenth rib anteriorly in the mid-axillary line. In this man it extends from the seventh rib to a point nearly in a line with the umbilicus. It is firm, hard, smooth and painless. The location of the long axis of splenic dulness, running from the axilla across towards the umbilicus, making an acute angle to the axillary line is diagnostic of enlargement of this organ. The suggestion that this man's trouble is due to leucocythemia must not be overlooked. The examination of the blood disproves this possibility. That this is not that form of pseudo-leucemia known as Hodgkin's disease, will be shown presently, in summarizing the forms of anemia. Arsenic and not quinine is indicated in such a case.

The study of the causes, diagnosis and course of the various forms of anemia is most interesting and important. In the

first place, in the consideration of symptoms common to all forms of anemia, is the study of pallor. Pallor, while a useful aid in diagnosis is not an unvarying sign of anemia. We can have considerable pallor in the patient, when the examination of the blood reveals the fact that it is normal in quality and quantity. Of the other symptoms, shortness of breath and rapidity of the heart's action are due to the lack of perfect oxygenation; especially is this true when the corpuscles, which are the oxygen carriers, are diminished in number or power. The coolness of the extremities is due to a similar cause; the giddiness to lack of proper nutrition of the brain. In the classification of the divisions of anemias, great confusion still exists. First, they are divided into two great classes: primary and secondary; the primary are those which exist at once, and are due to disturbance in the blood-making organs; the second follow the action of organic disease. A far better division of these anemias is into idiopathic and symptomatic; the idiopathic arising from the blood-making organs; the symptomatic being indicative of disease elsewhere.

Anemia is the want of blood; its diminution in quality or quantity. The constituents of the blood are so altered that it cannot perform its proper physiological functions. Symptomatic anemia appears in the course of such diseases as phthisis, interstitial nephritis, wasting due to starvation, etc. In phthisis it is true that there is some direct loss of material in the discharges; in interstitial nephritis there is some loss of blood in the albumin carried off in the urine; still the great source of anemia is in the disease itself. There is always defective assimilation and nutrition. In the toxemias there is symptomatic anemia, due directly to the destruction of the blood; such forms are seen in syphilitic, malarial, mercurial, arsenical and lead poisoning. In the other great division—the idiopathic anemias, there is definite change in the blood itself, associated with actual destruction of the corpuscles or with such change as prevents their production, hemolysis (?) or hemogenesis. The three great divisions of idiopathic anemias are chlorosis, pernicious anemia and the cytogenetic anemias. This latter form is divided into leucocytic and non-leucocytic, that is pertaining to the formation of leucocytes.

The distinction between symptomatic and idiopathic forms is as follows. There is some reduction in the number of red corpuscles in symptomatic anemia; the hemoglobin is not markedly reduced—the degree depending on the amount of red cells missing. There is no change in the character of the blood; no elements are gone, and no new ones are introduced. In idiopathic anemia there is definite change in the blood; there is diminution in the number of red corpuscles; in some forms there is increase in the number of white cells. There is diminution in the richness of the hemoglobin. Then the corpuscles change in appearance; instead of the red corpuscles being round, they are all sorts of shapes: larger, smaller, club-shaped, etc., forming the so-called Eichorst corpuscle. There is a change in the power of the red corpuscle to carry oxygen. The symptoms are the same as seen in symptomatic forms, differing only in degree.

In chlorosis, the number of cells remain about the same, there being a fall in the amount of hemoglobin, detected by the use of the hemoglobinometer. The use of such instruments of precision is essential in formulating a diagnosis; it is required for the definite discovery of the existence of chlorosis. In pernicious anemia, there is marked diminution in the number of red cells; these running down, in one report, as low as 143,000 to the cubic millimeter; 500,000 is a common count. The change in shape, size and form is more apparent.

The names of "progressive" and "pernicious" applied to this form of anemia are misleading. The disease is not always progressive, being occasionally intermittent, and patients sometimes recover. As more peculiar to this anemia are seen small, spherical corpuscles, Eichorst's being almost pathognomonic of this trouble. Nucleated red cells are also common. There are more marked clinical features than in chlorosis; the pallor is different in hue, yellowish, more suggestive of jaundice. There are some anatomical changes due to the anemia. Degeneration of the blood-vessel walls occurs; their tone is lost; a fatty degeneration of the intima occurs; subcutaneous or submucous hemorrhage follows. This is especially well seen on examining the eye-ground in the retina. With the hemoglobinometer an increase in the richness of the hemoglobin is found, despite the intense diminution in the number of red cells. This is a most striking difference between chlorosis and pernicious anemia.

In the third class, cytogenetic anemia,

we have the leucocytic and non-leucocytic. The leucocytic is further divided into the splenic, medullary and lymphatic. The principal anemia among the non-leucocytic is the so-called "Hodgkin's Disease." Here there is a hyperplastic enlargement of the lymph glands with the development of anemia.

Based on the combination of pathological, clinical and physiological research, Hunter, in London, has made a number of remarkable observations. This observer was anxious to determine the exact position of pernicious anemia. He found in the urine marked characteristics: a great destruction of the red cells producing a high color without alteration in the specific gravity. The spectroscopic and chemical examination revealed the fact that this pigment came from the disintegrated blood. There was found a great increase of iron in the liver, while there was less iron in the other organs. Normally there is a definite relation between the quantities of iron in the various organs. In malaria, pigment is deposited in the cells of the intima, along the course of the blood-vessels. In progressive pernicious anemia, it is deposited—not in the capillaries but in the liver-cells. It was thought at first that the liver took up the corpuscles themselves; but later it was proved that the liver-cells take up the pigment directly from the portal vessels. This condition is associated with carcinoma of the stomach, chronic gastritis, atrophy of the peptic glands, and other gastric and intestinal trouble. The reason for this is the development of specific ptomaines in the intestinal canal, due to the presence of parasites in this canal. Their destruction should take place in the portal circulation, depositing the iron in the liver. The injection of certain chemical substances into the blood will produce the same conditions artificially. In one sense this idiopathic disease is secondary to this process.

In the condition called paroxysmal hemoglobinuria, there is destruction of the blood with its appearance in the urine; with this may be associated intense anemia. Hunter found that these changes occurred in the general circulation, while in pernicious anemia, as we have seen, they are limited to the portal circulation.

—Lycopodium sprinkled on oiled silk prevents the fabric from adhering.

COMMUNICATIONS.

GENERAL CONSIDERATIONS ON THE FEVERS OF THE SOUTH.[1]

BY GEORGE DOCK, M. D.,
GALVESTON, TEXAS.

The study of the fevers of the South justly occupies a prominent place in the medical mind to-day. In every society meeting papers are read and discussions held; in almost every journal articles are published bearing on this theme. Everywhere there is great zeal, often close observation and learned reasoning. Yet it must be confessed, after a careful review of the subject, that no advance is made in the accurate knowledge of these diseases. But little is added to what we have long known of the nosology of the special fevers as they occur in our latitude, and no progress is made in clearing up the unsettled points regarding the anomalous or unclassified forms. In every meeting statements concerning even fundamental matters are met by counter statements; in almost every paper old hobbies are urged forward by vigorous hands, often, it seems, "with more desire for victory than for truth." Yet how seldom do we see the complete clinical history of a case, or an analysis of cases; how seldom a temperature curve; how seldom—nay, when do we see the account of an autopsy?

It seems, then, in order to secure better results, we must follow different lines, and in order to know more clearly what these shall be it is necessary to recognize and avoid the errors and short-comings of the past. The most important of these I believe to be the following:

1. Neglect to recognize and follow the general principles lying at the basis of the classification of fevers, and often the first principles of pathological anatomy and etiology.

2. Arbitrary or individual views of special morbid processes and a refusal to accept, for the purpose of organized work, the existence of certain conventional types.

3. A want of objective study, leading to inaccurate observation of cases and loose or general statements concerning them.

[1]Read at the meeting of the North Texas Medical Association, held at Sherman, Texas, December, 1890.

4. An entire absence of anatomical basis for theories or arguments advanced.

5. A tendency to apply novel and often unfounded theories of pathology or therapeutics to the subject.

Examples of each of these errors could be quoted from recent literature, but may with propriety be omitted.

In considering them in detail, we find a common example of the first kind exhibited by a perversion or confusion of certain technical terms, continued and remittent—terms of no value in the ultimate classification of fevers, but very useful clinically. This trait is due partly to an attempt, misguided, I believe, to do away with the distinction of meaning which the two terms should convey. That distinction was made long ago, but before the days of medical thermometry could not always be observed in practice—an objection not valid to-day, when the thermometer is consulted as regularly as the tongue. It is urged with some ingenuity that, as all remittent fevers are continued, in the sense of having no stage of apyrexia, one of the two words is superfluous. But one of the commonest kinds of remittent fever, the malarial remittent, is etiologically nearly related to the most common and characteristic intermittent, while the existence of fevers properly called continued cannot be denied. Now, as the question, whether the malarial fevers ever follow a continued course (in the narrow sense) has not yet been answered in the affirmative, there is great reason why both terms should not only be used, but be used with extreme care for accuracy, following the usage of correct writers. According to this a continued fever is one in which, during a part at least of the disease, the febrile temperature pursues a course modified only by such variations as occur in the normal condition—that is, a difference of not more than a degree Fahr. between the lowest and highest daily range. Closely related is the sub-continued type, where the variation is greater but not so much as in the remittent, when maximum and minimum differ by more than two degrees, without, however, reaching the normal.

This may seem a matter of subordinate importance. A more serious fault, the evil effects of which are hard to throw off, is a departure from the only safe guides to classification—anatomy and etiology. Hence it is that our fevers have as many names as they have local habitations, many of them unintelligible outside of certain localities. Another misconception of general principles is shown by the argument so often used, that a given disease cannot arise in a certain place on account of the absence of its supposititious causative germ. In the present state of our knowledge of pathogenic organisms, such arguments are of no value whatever.

Under the second heading, we find the neglect or refusal to accept the delineations of disease given by the masters of our art, and tested fully in the clear light of pathological anatomy. This is seen especially in connection with cases of enteric fever, which are so often the subject of needless controversy, on account of false ideas of its natural history.

In the same category belongs a refusal to accept as possible the occurrence of two diseases in an individual at the same time, important here because it leads to an erroneous position towards the compound affection called typho-malarial fever. This curious mental attitude is usually defended by an appeal to the authority of John Hunter and his "principle that no two different fevers can exist in the same constitution, nor two local diseases in the same part, at the same time." From this direct quotation (Palmer's ed., vol. iii, p. 3, *et seq.*) it is a question whether the "principle" would apply to the case in point, for it might be urged with great reason that one of the two diseases takes place especially in the blood, the other in certain organs of the abdomen. But the "principle" itself is so at variance with common observation, and with our present ideas of pathology that it is difficult to see how it can be seriously entertained. As a matter of fact, the mixed infection of enteric and malarial fevers, which was recognized by such unbiased observers as Dickson, Drake, Flint and many others, and worked out so impartially by Woodward, has gone through the final stages in the detection of the morbific germs at the hands of Kinyoun; and the question now is, not whether there is such a combination, but when, where and with what aspects it appears.

It is most unfortunate that the term typho-malarial is applied to a condition entirely distinct from the one just mentioned, viz., when a malarial fever assumes the typhoid condition, the word being used after the analogy of typhoid-pneumonia. When such a use is justified by facts (it has not yet been satisfactorily demonstrated that it ever is)

and the person using it makes his meaning clear, no great harm results, though the practice is not worthy of perpetuation.

Other errors are seen in the use of such terms as "catarrhal fever" for conditions very different from those described under that name in text-books, and often without notable catarrhal symptoms; "bilious fever" when there is no "biliousness," etc. Of course, owing to the difficulties of diagnosis, such terms serve a purpose in intercourse with the laity, but that they should be used in technical articles is a matter of distinct disadvantage.

In discussing the evils resulting from inaccurate observation, I speak with great reluctance. Skepticism of the observations of others, if carried too far, destroys all possibility of united work; and yet a great deal of erroneous observation and still more erroneous deduction takes place. Combined with arbitrary views of special diseases it has been productive of great confusion. As an example of this, the following experience, not by any means unique, may be cited: Some months ago a patient was sent from the interior of Texas to Galveston, with the written diagnosis of "continued malarial fever" from the local physician. This name, not used by systematic writers, is in common use in some parts of the country, and it is maintained by many who use it that such cases are neither malarial proper nor enteric. These cases are comparatively common in the place whence the patient came, so I think we may assume that the one under consideration represented the disease so called. In Galveston, however, the attending physician looked on the case as one of enteric fever, and when the patient died, a few days later, requested me to make an autopsy. At that I found the complete anatomical picture of enteric fever, without a trace of recent or old malarial infection. The specimens are here for your inspection.

This brings up the subject of anatomical investigation, the neglect of which is not altogether owing to prejudice against such practice on the part of the laity. It is an interesting fact that those who most strongly argue for the non-existence of old diseases and the occurrence of novel forms are those who pay least attention to the teachings of anatomy, though it cannot be said they do not have fatal cases in which to study it.

The application of novel theories in pathology do no great harm, but they seem to direct attention from the more tangible parts of the subject.

As intimated by the title, it was the object of this paper to call attention to facts of wide application, rather than to discuss the minutiæ of special pathology and differential diagnosis. Yet there are many things in these latter branches too often neglected in the study of our fevers, especially some aids furnished by modern instruments of research—the microscope in particular.

To sum up in a few words the best means of increasing our knowledge of fevers, I would suggest, in the first place, a familiarity with the classical description of fevers given by clinicians whose experience and judgment make them authorities, controlled and extended by observation at the bedside and the autopsy table under experienced instructors. Next, an objective and critical study of every case of fever, with the assistance of all the methods of exact diagnosis; and a thorough study of every fatal case, with the application of all the modern means of investigating anatomy and etiology. Working on these lines; keeping the anatomical limit where possible, and, where not, preferring rather such non-committal terms as "simple continued" than those expressing supposed etiological or anatomical characters, a comparatively short time would show such progress in diagnosis, with consequent increased certainty in treatment as has not been attained by following subjective methods.

THE CURETTE IN FISTULA IN ANO.[1]

BY BEN. BRABSON CATES, M. D.,

DEMONSTRATOR OF ANATOMY AND OF OPERATIVE SURGERY IN THE TENNESSEE MEDICAL COLLEGE.

All patients naturally loathe the idea of a cutting operation, be it ever so slight, and will undergo a great many inconveniences as well as endure an immense amount of suffering, rather than submit to the surgeon's knife. While I would not be understood as belonging to that class of physicians who are slow to use the knife when circumstances demand it, yet in certain cases of fistula in ano I should endeavor to effect a cure with the curette, which in the end is a cutting

[1] Read before the Knox County Medical Society, at Knoxville, Tenn.

operation, as it effects a cure by scraping away the tough and thickened pyogenic membrane, thereby substituting for it a healthy surface which heals readily. Moreover, the term "curette" is better received by the patient, who is ignorant of its real nature. Indeed he will actually regard it with favor, and gladly welcome it as a substitute for the knife.

In offering to the profession this mode of curing fistula in ano, I do not claim for it any superiority over the knife, or that it will ever supersede it (believing, as I do, in cases which will never be cured except by a resort to the knife or ligature); nor do I come with a long list of cases cured by this method; but I present the subject on its merits, hoping that, like "seed sown in good ground," it will find a nidus in a fertile spot, which will give us, at some future time, sufficient data upon which to base an opinion in subsequent cases.

The cases for which I would recommend the curette in the treatment of fistula should, for obvious reasons, be select: such as incipient fistula in ano, or those cases after a resort to the knife in one or more sittings, in which healing has taken place in all portions of the wound except at a small tract no larger than a knitting needle or a crow's quill; or even in cases of fistula with two or more sinuses it might be tried. Again, I think it is applicable in cases in which the fistulous tract shows a tendency to fill up from the bottom, and buoys the hopes of the surgeon to that point where he thinks he can dismiss his patient as cured, but in which he will notice after careful examination the least possible drop of pus at some portion of the cicatrix, and should he attempt to examine it with the probe, will find to his horror that it passes into a cavity of considerable size, which is generally barrel-shaped or fusiform. Here it is that the curette is of especial value, as in the following case, sent me by my esteemed friend, Dr. J. M. Kennedy.

The patient was a negro man, about twenty-two or twenty-four years old, and a laborer, who had been troubled with fistula in ano for two years. On examination, I found a large abscess cavity on the left buttock, with four openings, all discharging a thin offensive fluid, and one sinus extending into the rectum, just within the verge of the anus. On November 14, 1889, in the presence of Dr. Kennedy, I laid open the abscess cavity and all sinuses leading into it, washed it out thoroughly, and packed it with lint. The abscess cavity had a worm-eaten, or honey-comb appearance, and was covered with a thin, dirty-looking exudate. The cut edges of the wound were exceedingly rotten and, on pressure between the fingers, could be readily crushed like a mushroom. I saw the patient each succeeding day for the first week, and then gradually lengthened the number and frequency of my visits, washing out and packing the wound each time I saw him. The wound healed readily except a single fistulous tract, which extended up in the ischio-rectal fossa for about two inches.

On December 20, I again operated, making a complete fistula by pushing the grooved director through the gut into the rectum above the internal sphincter, bringing it out at the anus, and dividing all the tissues on the director; afterwards I stuffed the cavity with lint as in the previous case, after having thoroughly curetted it. This second operation was followed by incontinence of feces and an involuntary escape of flatus, which disappeared however in a few days. The wound healed rapidly, except the fistulous tract, which was unclosed as before the operation.

On March 13, 1890, after having injected a drachm of a saturated tincture of iodine into the fistula, I placed the patient on his feet and let him walk about, he having been in bed for nearly four months. On March 15, I gave another injection of the iodine solution, with negative results. On March 27, I injected a four per cent. solution of cocaine into the fistula, which deadened sensibility completely; then, taking my probe-pointed bistoury, I enlarged the opening leading into the fistula sufficiently to introduce a curette, and having thoroughly scooped it out and irrigated it with simple pure water, I packed the wound with lint. I dressed the wound each succeeding day. On May 3, I repeated this operation, and again on June 2, all the while allowing my patient to go about and do as he pleased. On June 23, after having examined the wound and found it had healed in every part, I dismissed the patient as cured; and he remains well to this day.

The main reason I have for presenting this paper before this Society is to show that, even after one or more cutting operations have failed, or the application of a strong irritant is *nil*, a cure may be obtained by other means than the use of the knife or

an irritant. Again, when, after repeated failures, the surgeon may be unwilling to recommend another formal operation to a doubting patient, and thereby risk establishing incontinence of feces or incurring the reproaches of an ungrateful patient, he may have recourse to the curette; which his patient will readily submit to, more especially, if assured that it will be a painless procedure.

Therefore, after having thoroughly tested the curette, in a case which had not only resisted the knife in two formal sittings and two applications of a strong irritant, but had also tried the souls of both physician and patient, I am persuaded that, in certain select cases, such as incipient and external blind fistula, etc., the curette will in the future be the means of curing a good many fistulas, and will thus deliver our patients from that horror of men—the knife.

DIPHTHERIA.

BY C. W. MUSGROVE, M. D.,
LOCK HAVEN, PA.

Diphtheria, in its pathological relations, has been and is still quite complicated in some respects. However, one important factor—the cause—seems to have been settled as being a diphtheritic microbe. But there still remains an important point to be determined. All our leading pathologists agree that two distinct conditions exist: the local and the constitutional, in an individual afflicted with this diphtheritic microbe. But which is primary and which is secondary, is the question that agitates the minds of the pathologists to-day. The opinion of Loeffler on this important question is worthy of serious consideration. He says: "The bacillus is abundant in the pseudo-membrane, but is not found in the blood-vessels, lymphatics or internal organs; so that its pathogenic action must be localized on the surface. If it be the specific principle, it must act by producing a poison where it is localized, which poison causes neurosis and dilatation of the vessels, from which lymph exudes, and entering the lymphatics and circulatory system causes systemic infection." W. Watson Cheyne recognizes the importance of Loeffler's researches and thinks it probable that the micro-organism which causes diphtheria is a bacillus, which, lodging upon the throat, is propagated there. Having upon the mucous surface a favorable nidus for its development, it not only lies upon, but also penetrates the superficial portion of the mucous layer, and causes the exudation of fibrinous material. He furthermore believes it probable that the bacillus produces very poisonous ptomaines, which, entering the circulation, give rise to general systemic infection. That the bacillus is the causative agent of diphtheria is rendered probable, and that systemic infection by the diphtheritic poison is not produced directly by the entrance of the microbe into the circulation, but by ptomaines which spring into existence through the agency of the microbe, is also the opinion of some of the highest authorities in the study of bacteria. It seems to be accepted as a fact that this microbe is capable of setting up a local diphtheritic action in any portion of the body where it finds an inflamed, denuded or cut surface upon which to lodge; also that the microbe requires favorable surroundings for its nidus and propagation. Is it not then probable that this diphtheritic microbe requires the identical material found in the throat; such as saliva, etc., in connection with the results of catarrhal affliction in said region, which are so very prevalent? The principles of medicine teach that, as a rule, two causes are necessary for the production of disease: the predisposing and the exciting cause; also that a resisting force exists in the constitution under peculiar conditions.

Diphtheria is classified as an extremely contagious disease; however we frequently find persons fully exposed to its morbid influence who escape its evil effects entirely. On the other hand, we find persons only slightly exposed, who become victims of the disease in its most severe form. In such instances we have a complete manifestation of a resisting force, and the predisposing and exciting causes displayed; now if this resisting force did not exist in the individual, all persons exposed would be sure victims of the disease. This of course applies not only to diphtheria, but to all contagious, and even to other diseases. In diphtheria we find the constitutional, and local condition markedly distinct; so much so, that a person may have the disease locally, beyond doubt, with the constitution but slightly affected. We know, futhermore, that diphtheria never exists as a constitutional disease unless the local disease is present.

But that the local disease can exist with-

out affecting the constitution, but very slightly, we also know. In no contagious disease do we have the same opportunities for observing and comparing local morbid conditions with the constitutional condition, as in diphtheria. Membraneous croup does not present the same opportunity, for the reason that the local condition is more out of sight. It is true that the local predisposing cause is present in the throat, but the constitutional effect is that which is produced by any interruption in the function of the lungs, while in diphtheria we have the neurasthenic condition to contend with in the general system. In other diseases we have the predisposing cause in the individual for the exciting cause to act upon. But when such is the case, if is from the fact that the constitution is rendered vulnerable by some abnormal condition existing in the blood or organs, this producing the predisposing cause. In diphtheria we may have the predisposed cause in the throat as a local catarrhal inflammation or even a denuded surface. It is fully accepted as a fact that the diphtheria microbe will attach itself to a denuded surface in any part of the body, and the throat being subject to slight catarrhal inflammations at least two-thirds of the time, the throat is a most suitable nidus for the diphtheritic microbe, and it is in the throat that the physician finds the first physical sign with which to make the diagnosis of diphtheria. When we consider the principles of medicine in connection with the opinions of authorities such as Loeffler and Cheyne, who declare, that they believe the bacillus to be the exciting cause of diphtheria, and that they have never found the bacillus beyond the psudo-membrane in the throat, we have excellent reasons for concluding that the local or throat conditions in diphtheria is primary, and the constitutional affection is secondary. From this it follows that our aim in treatment should be to suppress the local condition and to support the constitution in its resistance to the invasion of the poison.

—In using chloroform as an anæsthetic the decomposition of the vapor in the presence of artificial light, especially gas, produces irritating and noxious fumes. These have been analyzed by Kunkel and found to consist principally of hydrochloric acid. Where free ventilation is not possible, water or lime-water, or a solution of soda, exposed in a basin or sprayed will neutralize the acid.

DISEASES OF THE EYE ASSOCIATED WITH CARIES OF THE VERTEBRÆ.[1]

BY JAMES K. YOUNG, M. D.,

INSTRUCTOR IN ORTHOPÆDIC SURGERY IN THE UNIVERSITY OF PENNSYLVANIA; ATTENDING SURGEON, ORTHOPÆDIC DEPARTMENT, UNIVERSITY HOSPITAL, ETC., ETC.

The diseases of the eye, associated with caries of the spine, are, from necessity, of the same pathological nature—strumous or tubercular. The occurrence of ophthalmic affections, in certain cases of spinal caries, has frequently been observed, and the direct association has been frequently noted. It is impossible, in this connection, to sketch the more important lesions met with; suffice it to mention the various affections, pointing out those which have a particular significance bearing upon the relationship existing.

Among the most frequent diseases affecting the lids and lachrymal apparatus are the various forms of conjunctivitis (acute and chronic), eczema, lupus or *scrofulide tuberculeuse*, and dacryocystitis. Of these, lupus is one of those lesions which may be the only evidence of a tubercular condition, and although its tubercular nature has been doubted by Kaposi, for well-known reasons ("because of the paucity of the bacilli in the morbid changes, the non-appearance of general tuberculosis in the same individual after a long duration of the lupus, the impossibility of multiplying lupus by inoculation, and the almost universal immunity from lupus of other members of the same family")[2], anatomically it contains tubercle-bacilli; and tuberculosis can be reproduced by its inoculation. The presence of lupus is peculiarly significant of struma.

Affecting the anterior portion of the globe is that peculiarly interesting affection—phlyctenular disease, and phlyctenular keratitis, with their periods of exacerbation and improvement, almost peculiar to the strumous diathesis. Hypopium keratitis, ulcus corneæ serpens, as the result of dacryocystitis, episcleritis, scleritis, sclero-keratitis, and even staphyloma of the sclera, are met with as direct evidence of a scrofulous dia-

[1] Read before the American Orthopædic Association.

[2] Jacobi, *Keating's Cyclopedia of Diseases of Children*, Vol. ii, p, 173.

thesis. Particularly significant in this portion of the eye is the so-called iritis serosa—formerly known as Descemetitis, a strumous lesion of the iris, involving frequently the ciliary body and deeper structures; and tubercles of the iris, or, as it was formerly called, *granuloma*.

The former affection, or scrofulous iritis as Vernon[1] called it (retaining the name employed by Mackenzie and others), has not received, in late years, from ophthalmologists, the attention it deserves. In fact, Vernon has spoken particularly of the unsatisfactory and inexact state of our knowledge as regards tubercular affections of the eye in his former paper.[2] The nodules attached to the iris in this disease, upon microscopical examination, have been found to consist of "small nucleated cells, with many free nuclei, and a very scanty intercellular stroma, with *débris* of cells, but without blood-vessels or pigment." These cases cannot be classed in the category of iritis, as generally observed, on account of the early age at which they make their appearance, the futility of therapeutic measures, and the danger to life.

The true tubercular affection resembles somewhat the serous iritis in general course, symptoms, etc., and may even terminate in destruction of the globe. The tubercles of the iris found in this disease, and formerly described as granuloma, differ, however, essentially from the nodules found in serous iritis; but their true nature is perfectly identified by recognizing the characteristic bacilli. The posterior portion of the eye, or deeper structures, are less frequently affected, and when diseases do occur as primary lesions, they present no distinctive features. Among these may be mentioned tubercles of the choroid, as a result of general miliary tuberculosis, and especially of tubercular meningitis; and choroido-retinitis, alone, or associated with optic-neuritis.

It will be observed in this enumeration of the diseases of the eye associated with spinal caries, that the majority, and certainly the constant ones, are all of the strumous or tubercular nature; and this introduces us to the relationship of these two conditions and the significance of these diseases to the osseous lesion progressing within. Referring to the relation between scrofula and tubercle, Treves has given the following conclusions:[1]

1. The manifestations of scrofula are commonly associated with the appearance of tubercle; or if no fully formed tubercle be met with, a condition of tissue obtains that is recognized as being preliminary to tubercle. *Anatomically*, therefore, scrofula may be regarded as a tuberculous or tubercle-forming process.

2. The form of tubercle met with in scrofulous diseases is usually of an elementary and often of an immature character, whereas in diseases called tuberculous in a strict clinical sense, a more perfect form of tubercle is met with in the form of the gray granulation or adult tubercle. (Grancher.)

3. Scrofula therefore indicates a milder form or stage of tuberculosis, and the two processes are simply separated from one another by degree.

Accepting this view there is, in other words, in scrofulous persons a constitutional predisposition to caseation, or a tuberculosis of irritated parts. When the bacillus tuberculosis is actually present in the diseased area, scrofulosis has been succeeded by tuberculosis. In etiology most of these diseases of the eye are scrofulous rather than tubercular, possibly from the fact that, being more superficial and accessible, attention is earlier directed to them.

In this connection it is interesting to observe an antagonism, not absolute, but tolerably well established, which seems to exist between the external and internal tubercular processes. This is why phthisis is not more frequent in subjects of hip disease, why subjects with external cervical gland disease are not more often attacked with pulmonary tuberculosis, and why subjects with angular curvature (caries of the vertebræ) are not more commonly attacked by it. It is because of this apparent antagonism that exists between the tubercular diseases, that it is, moreover, unusual for two grave manifestations of scrofula to be active at the same time—one will become manifest, while the other is observed to improve or subside. This observation is particularly to be noted in the associations under consideration. It is common to observe the ophthalmic diseases improve or subside altogether while an exacerbation of the osseous affection supervenes, and *vice versa*. It may be considered, then, as established that the majority

[1] Vernon, *British Medical Journal*, 1874, Vol. ii, p. 276.

[2] *St. Bartholomew's Hospital Reports*, Vol. vii.

[1] *Scrofula*, etc., London, 1882, p. 21.

of cases of spondylitis are tubercular; that the etiology of these diseases of the eye and of the caries is the same (*i. e.*, insufficient diet and infection); and that they are both liable to exacerbations.

These facts taken altogether have a peculiar significance, and indicate a prophylaxis and a necessity for treatment which might otherwise be overlooked.

There is constantly going on, in the economy, a warfare by the active, healthy, cellular structures which compose the human organism, against the invasion of parasites. Whether the claim of Metschnikoff be accepted, that the degeneration of the bacilli (which has long been known to occur within the giant cells), results directly from this phagocytic action; whether the statement of Baumgarten be admitted, to regard the relation of the giant cells to the bacteria as one of the strongest evidences against the theory of phagocytosis; or whether the agnostic expression of Osler be taken as the present state of our knowledge—the indication to employ both constitutional and local treatment deserves emphasis.

In conclusion, if this short paper convert but one practitioner to the importance of treating all localized tubercular lesions with constitutional as well as local treatment, the object for which it was written will have been accomplished.

To summarize, then,

1. The diseases of the eye associated with caries of the vertebræ are scrofulous or tuberculous.

2. Scrofulosis is a predisposition to caseation; tuberculosis is the infection with tubercle bacilli.

3. Both the diseases of the eye and the caries of the vertebræ require constitutional as well as local treatment.

Reports of Clinics.

BUFFALO GENERAL HOSPITAL.

MEDICAL CLINIC—DR. CHAS. CARY.

The first patient had been before the class already. He was admitted two months ago, suffering with uremic poisoning. At one time the urine fell to 170 c. c., with 4 grams of urea in the twenty-four hours. Dr. Cary said that he was brought before the class now, more to show what humanity can endure than for further elucidation of the case. He had had œdema and ascites, which gradually diminished as the condition of the urine improved in quantity and quality. Albumin was still present in large amount. The first examination impressed Dr. Cary with the idea that there was something behind the maladies which were apparent, and he had therefore examined him daily, and every two or three days there had been some new development. He had had pericarditis with a most marked friction sound, which disappeared before the day on which the ward-class was to examine him, but which had reappeared, and it was now heard indistinctly. He also developed endocarditis. The liver was at one time lower than normal; then it returned to its normal position; and now it was down again. The liver was depressed in position rather than enlarged, and the change of position was due to the varying quantity of fluid in the right chest—for the man had had pleurisy of both sides with an abundance of effusion. The presence of pain and fever and the development of inflammation of the endocardium and pericardium determined the diagnosis of pleurisy instead of hydrothorax. The man also had a pneumonia of the left lung.

The patient was a mere shadow of his former self. When first presented to the class his legs were enlarged from the dropsical effusion; now there had been not only an absorption of the effusion, but also a wasting of the muscles, so that he was reduced almost to a skeleton. During the course of the pericarditis he had received small doses of opium and mild counter-irritation, about rather than over the pericardium. The effusions had been carefully watched, so that aspiration might be performed if necessary; but they had been reduced by salines instead, and when they had become slight nothing had been done for them. On account of the chronic renal disease, there was no prospect of the patient's recovery, and the fact that his life had been prolonged by good nursing and symptomatic treatment was really no benefit to one in his deplorable condition.

Rheumatoid Arthritis.

The next patient was a single man, thirty-four years old, though appearing much older. He was born in Buffalo of Irish parents. He had been a hired man on a farm. His family history was wholly negative. He had enjoyed fair health until two years ago. Five

years ago, while killing hogs, one of the pigs pressed his right knee against a pump-spout, causing considerable pain but no disablement at the time. Two weeks later the knee became sore and slightly swollen on the inside. He did not consult a physician, but relieved the pain and swelling by using a liniment. The knee gave him no further trouble for two years, when the symptoms returned spontaneously but without confining him to the house. The knee improved, but did not become entirely well; and a third attack confined him to bed for three or four weeks, the right knee being much inflamed and swollen, and the left participating to a less degree. A physician aspirated both joints. Even before the knee-joints were so badly swollen as to need tapping, the wrists, elbows and right ankle began to swell.

The man had had gonorrhœa eight years ago, lasting seven days, and without recurrence. The beginning of his trouble could not, therefore, be a gonorrhæal synovitis. His countenance, sunken eyes, flushed cheeks and coated tongue indicate that he is suffering from some constitutional disturbance. His left pupil was shaped like an old-fashioned kite, curved above and coming to a V below. This suggested iridectomy, but the man said the condition was congenital, and that the vision of this eye was better than that of the right. Syphilis was denied.

The knees were much enlarged, the patella was three or four times its normal size and the swelling, especially at the inner side, was soft and fluctuating. Under the finger there were movable masses, undoubtedly of cartilage, which could be chased around by the finger. There was a parchment-like crackling. The legs were markedly atrophied.

A similar enlargement was present to a less degree in the ankles, wrists, elbows and metacarpo-phalangeal and many of the interphalangeal articulations. There was also muscular atrophy of the arm and forearm.

This, said Dr. Cary, is the disease called rheumatoid arthritis or arthritis deformans, or, by some, rheumatic gout, which is not a classical name. It is an essentially chronic disease prevailing much more among the poorer classes than among the well-to-do; for which reason it has been described as the arthritis of paupers. A clean-cut differentiation between this disease and rheumatism cannot be made, any more than between acute and chronic rheumatism. If this man had been brought before a class two years ago, he might have been used to illustrate chronic rheumatism, and his first serious attack of inflammation might possibly have been erroneously described as acute articular rheumatism; but at this stage the diagnosis is unmistakable.

Rheumatism is a disease that attacks only fibrous structures, sometimes the synovial membrane, sometimes the ligaments of a joint, sometimes the pericardium, heart-valves, pleura, etc. Chronic articular rheumatism damages a joint more by the production of fibrous ankylosis than by causing any definite pathological alteration. In this disease there is an absolute inflammatory growth of bone. There is an inflammation of the cartilages, so that they enlarge and form nodules projecting into the joint cavity under the synovial membrane, and fragments may then break off and lie loose in the fluid of the joint. The deeper layers of cartilage become more bony, and the superficial layers soften, so that the cup which the cartilage forms on the end of a bone becomes deeper. There is an enlargement of the ligaments about the joint, and even the synovial fluid is increased, and it is usually thick, dark and almost mucoid. Later in the disease the muscles take on spasmodic contraction. This man has never had cramps; but, as he stands, the muscles of the leg are in a state of tension, and complete extension of the leg is impossible. The elbow also cannot be flexed and extended as widely as it normally should.

This disease was described even in the last century, although under a different name. The cases are usually not seen so far advanced as this one.

What is the poison to which the disease is due? Many contradictory answers have been given. Some claim that it is due to sepsis, citing those cases which begin with gonorrhœal arthritis as proofs. Others say that it is tubercular, one member of a family having this form of arthritis while another has typical tuberculosis. It is not probable, however, that there is any such close connection, although tuberculosis may arise in a joint already diseased in this way. Others claim that it is due to faulty nourishment, bad air and unfavorable environment. This is certainly true; but is not a complete explanation.

Not uncommonly the heart is diseased along with the rest of the connective tissue structures. This patient has a mitral regurgitant and an aortic obstructive murmur.

Treatment is not very promising, mainly because the persons affected are usually unable to follow the directions which would naturally be given. Massage, sojourns at Vichy, Carlsbad, Saratoga, etc., are quite beyond their means. The taking of plenty of good rich food is beneficial—quite the contrary of the indication in rheumatism. Iron is serviceable. The skin, bowels and kidneys should be kept active.

Acute Endocarditis.

The history of this patient was as follows: J. G., twenty-five years old, single, born in this country of Irish parents, laborer. His father, fifty years old, had had rheumatism a great deal. The mother died at the age of thirty-six years, of some acute disease. Four brothers and one sister were alive and in good health. The patient had had varioloid and measles in childhood, malarial fever eight years ago, gonorrhœa six years ago, chancroid or perhaps chancre five years ago.

He had indulged for six years in periodical sprees. His general health had been good. About four weeks ago he got wet and took cold. He became better, but then had pain in the back and shoulders, which were still lame and painful. He had been rather short of breath for about a year. His urine was yellow, faintly alkaline, urinous in odor, with a specific gravity of 1.017, depositing considerable white sediment, but without albumin or sugar. The man's temperature on admission was 98.2°, his pulse 94, his respiration 20. He had an eruption on his arms which he said came out when his blood was out of order. He had been taking "blood medicine." There was a history of a sore on the penis, which was described as a soft chancre. His hair had not fallen out, nor had he had sore throat, etc. Dr. Cary said that he probably had had syphilis.

When he entered the hospital the man had a loud mitral regurgitant murmur, and as there was no cardiac hypertrophy, and as he never had rheumatism before, acute endocarditis was diagnosticated. Rest and salicylates were ordered, and later iodides were added. He had lost the pain in his arms and shoulders and the murmur had almost disappeared.

—The Malabar nut of East India is in vogue amongst the natives as a cure for scald-head and other microphytic skin diseases.

PERISCOPE.

Treatment of Hemorrhoids.

In an article in *The Cincinnati Lancet-Clinic*, November 29, 1890, Dr. L. J. Krouse gives a summary of the treatment of hemorrhoids, in which he says:

The ligature dates its origin back to the time of Hippocrates. His method consisted in applying a woolen thread as ligature to the base of the tumor, and then cutting off the strangulated mass. This method, with some improvements, has been handed down to our own times, and has been brought more into favor by Allingham. His method is to have the bowels first thoroughly moved by a cathartic, and shortly before the operation a large enema should be given, both for its cleansing effect as well as to bring the piles well into view. While the patient is straining, each pile should be caught separately by a tenaculum. Acting on the anatomical knowledge that a pile is supplied by a blood-vessel which enters from above, he cuts the pile loose from its attachment below and then dissects up the mass to about the point where the blood-vessel enters. A ligature is then thrown around the pedicle and the mass is cut off. If the pile is very large, it is divided into two or more segments by transfixing the mass with a needle armed with a ligature, and each segment is separately tied. The stump is then returned within the sphincter. This method is the one that is most commonly used, and requires from ten days to two weeks' confinement to bed, and frequently necessitates the use of the catheter.

The clamp and cautery method was first used in London, in 1848, by Mr. Lee. His plan of treatment consisted in applying a clamp to the base of the tumor, cutting off the greater portion of the protruding mass, and then applying nitric acid to the raw surface. Mr. Henry Smith, of the same city, has used this method for many years, and has improved it by using the actual cautery instead of nitric acid to the raw surface. "The method of using the clamp," he says, "is very simple, and consists of the following manœuvre. The diseased portions, being well brought down previously by an injection, are separately seized with a vulsellum and handed to an assistant. The part is then enclosed within the blades of the clamp, which are screwed home quickly and thoroughly. The prominent portion of the

pile or prolapsus is then cut away by a sharp pair of scissors. The cut surface is next dried by a piece of lint or sponge, and either nitric acid or the actual cautery, so shaped as to come into contact with the whole of the raw tissue, is applied. When this is effected the blades are gently and slowly unscrewed, and, if there is no bleeding, the part is well oiled and allowed to return within the cavity of the gut; if, however, any bleeding point is seen, the blades are quickly screwed together and the cautery applied until the vessel is thoroughly sealed up. The finger is then introduced well up into the rectum. This step serves the triple purpose of returning all the parts well, of compressing any point which may possibly bleed, and of exciting the sphincter to healthy action."

More formidable than either of the preceding methods is that which goes under the name of Whitehead's operation. It consists of the removal of the entire pile-bearing region. A circular incision is made around the anus at the junction of the skin and mucous membrane, and an inch to an inch and a half of the mucous membrane of the lower part of the rectum is removed. Only the affected and diseased mucous membrane with some of the submucous tissue, is excised, the other coats of the gut not being interfered with. The healthy portion of the mucous membrane above is then brought down and is attached to the skin of the anus. An ideal surgical procedure! This operation is limited to those cases of severe type, where the whole circumference of the gut is studded with piles.

Leaving these more severe surgical operations, which require the patient to be under the influence of an anæsthetic, we come to the simpler methods, which ean be readily done in the physician's office, and which most physicians rather prefer, as no blood is spilt.

The injection method consists of injecting a certain amount of a coagulating fluid into the pile by means of a hypodermic syringe. Different surgeons use different fluids. Kelsey employs carbolic acid in 15, 33, 50 and 95 per cent. dissolved in water with enough glycerine to keep the solution clear. Dr. Fenn's solution consists of equal parts of fluid extract of ergot and a 95 per cent. solution of carbolic acid. Dr. Washburn uses a solution of carbolic acid in sperm oil in the proportion of 1 to 2 or 1 to 4, depending upon whether he wishes to produce sloughing of the tumor or only induration. Givard employs a solution consisting of tannic acid one part, carbolic acid two parts, alcohol four parts, and glycerine eight parts. The injection fluid used by those that follow the so-called "Brinkerhoff system" is composed of carbolic acid ℥i, olive oil ℥v, and zinc chloride grs. viii.

Electrolysis has been used to destroy these tumors. The positive electrode, which is a needle, is introdnced into the centre of the tumor, while the negative pole is placed on an indifferent portion of the body. A current strong enough to produce a caustic effect should be used.

Having mentioned the various modern methods in use for the destruction of these tumors, it behooves us to analyze which of them is the safest for the patient, and which will cure him in the shortest time.

Henry Smith, in his report of over four hundred and fifty cases, in which he applied the clamp and cautery, not only to hemorrhoids, but also to prolapsus, states that he has lost but two cases. In only one of these cases was death due directly to the operation, the patient suffering from a prolapsus of such extent as to bring down part of the peritoneal covering of the bowel; this caused secondary peritonitis with fatal issue. He condemns the method of ligation, saying that it is often followed by ulceration, tetanus, pyæmia, and occasionally by death.

Bodenhamer, although not agreeing with Mr. Smith in his general condemnation of the ligature, still says that "the method by clamp, scissors and actual cautery, is the best and safest, and should be preferred if ever such an operation is resolved upon."

Kelsey now uses almost entirely the clamp and cautery, and says that after ligating these tumors, according to the plan of Allingham, he often found his patients suffering great pain, which lasted from eight to ten days, and that he was frequently compelled to use the catheter for several days. Since using this method, his patients are almost entirely free from pain and seldom has he need to resort to the catheter. The convalescence is shortened, the patient being up on the second or at most on the third day. According to Mr. Smith the patient so treated leaves the hospital on the fourth, fifth or sixth day.

Van Buren says that "the actual cautery, with our present facilities of applying it, stands very nearly on a par with the ligature."

As regards the injection plan of treatment, most authorities who were at first highly pleased and enthusiastic over it, have, after their first enthusiasm passed away, given up this method almost entirely.

It was claimed by those who used this method that it was safe; that it was free from pain, and that it necessitated no confinement from work.

On the contrary, Dr. Matthews declares "that it is painful, insufficient and liable to cause death by peritonitis, embolism and pyæmia."

Allingham says that he has "tried the injection plan, but the result was much pain, more inflammation than was desirable, a lengthy treatment, and the result doubtful; certainly not a radical cure."

Kelsey, who at first was an enthusiast, is not so now, and rarely uses it unless in selected cases. He claims that sloughs, marginal abscesses, lymphangitis, ischio-rectal abscesses and deep fistula frequently follow, but has never seen a fatal case.

Andrews states "the method is moderately, put positively dangerous, and we cannot recommend it as proper in ordinary cases." In 3,304 cases collected by him, he finds that there were 13 deaths: embolism of the liver, 8; abscess of liver, 1; dangerous hemorrhage, 10, permanent impotence, 1; stricture of rectum, 2; violent pain, 83; severe inflammation, 10; sudden and dangerous prostration, 1; carbolic acid poisoning, 1; failed to cure, 19; sloughing and other accidents, 35.

In conclusion Dr. Krouse says that judging from the views expressed by well-known authorities, and from his own experience, he believed that good results may be obtained by any of the surgical methods mentioned above. He says that he has a preference for the clamp and cautery operation, which seems to him to be the safest, producing a good result in a short time with the least discomfort to the patient. In cases, however, in which the patient absolutely refuses the major operation he would not hesitate to employ the injection plan, using, however, the weaker solutions.

Meat Preservation.

Dr. Hans Beu, in the *Centralblatt für Bakteriologie und Parasitenkunde*, points out that nearly all the newer methods of preparing preserved meats have had to give way before the older methods of boiling, drying, salting and smoking, which, along with freezing, preserve the taste and digestibility of meats better than any of the chemical methods that have more recently been recommended. All these old methods, he maintains, hinder decomposition and keep meats eatable for a longer or shorter period. Cold acts by preventing putrefactive changes in meat, 2° to 4° C., with good ventilation, preventing the development of most organisms. Boiling with subsequent exclusion of air is, of course, good, but can only be carried out in large establishments and under specially favorable conditions. Drying gets rid of the water, without which micro-organisms cannot develop, but, although there is no loss of albuminoid or salts when this method is used, the taste is somewhat impaired. Salt also acts by removing water, but it also removes the extractives, and interferes with the delicate flavor of both meat and fish. Smoke acts partly by drying, the heat at which it is generated rendering this necessary, but partly, also, by the action of the small quantities of the antifermentative constituents, such as creasote, carbolic acid and even volative oils, which appear to have a direct action on the vitality of putrefactive organisms. The author agrees with Förster, that salt has little or no effect upon most pathogenic organisms, but it undoubtedly interferes with the development of the cholera bacillus and of anthrax bacillus that contains no spores, and probably, also, of some of the non-pathogenic but putrefactive forms. As the result of his experiments on a very large number of food materials, such as ham, bacon, pork, various kinds of sausages, and fish, Beu comes to the conclusion that most meats are salted not only to preserve the taste, but also to withdraw a large proportion of the water from flesh; that smoking also withdraws a considerable quantity of water, that it hides the salty taste, and that, being able to penetrate dried flesh, it is better able to exert its antiputrefactive action than on fresh meat. Salted lean flesh, exposed to the action of smoke at from 22° to 25° C. for forty-eight hours, no longer contained liquefying organisms, which had been present in considerable numbers before the smoking operation was commenced, but non-liquefying organisms disappeared only on the ninth day of smoking. Salt bacon salted for ten days, and then exposed to the action of smoke for forty-eight hours, also showed no liquefying

organisms with a fragment from near the centre taken with the most strict precautions, and broken up in liquid gelatine, which was afterwards allowed to solidify. All non-liquefying organisms had disappeared on the seventh day of smoking. Bacon salted for five weeks contained no organisms after seven days' smoking. Fresh unsalted meat contained both kinds after six days of smoking, and sausage also contained both at the end of twelve days; this being exactly in accordance with what would be expected from the large amount of water that is contained, from the nature of the meat used, and from the many manipulative processes through which it has to go before the smoking is commened. Fish may be preserved for a short time by smoking only, but it could not be kept permanently. Hams and larger sausages require a longer period of smoking than do similar smaller articles of diet.—*British Medical Journal, Supplement*, November 22, 1890.

Small Doses.

In the *Edinburgh Medical Journal*, December, 1890, Dr. J. L. Porteous praises the use of small and repeated doses of a variety of drugs, among them gelsemium, calomel, opium, nux vomica, and nitroglycerine. Speaking of the assayed fluid extract of gelsemium he says: "I have found wonderful benefit derived from the use of this medicine in minute doses—say five drops of the extract in four ounces of water, one teaspoonful of this every ten minutes for one hour, then every hour. When I first read of this mode of administration of the drug I was sceptical, but at the same time was determined to try it. I had an early opportunity, which presented in the form of threatened pneumonia. The condition of patient was as follows:—There were minute crepitations; pain in lungs; temp., 104°; pulse, 130; skin hot and dry. After two hours' treatment, as above, the skin became moist, temperature and pulse were reduced, and what appeared to be the commencement of an attack of pneumonia averted. If aconite in same proportion be added, the results are even more satisfactory.

The drug is powerful. Five drops may cause double vision and other toxic symptoms, but when given in minute doses these symptoms are avoided, and the beneficial effects of the medicine only are produced. Of course this medicine is not infallible, and Dr. Aulde thinks that if it does not relieve within twenty-four hours it ought to be discontinued. He has found it of service in the neuralgic pains of dysmenorrhœa."

Calomel, in small doses (gr. $\frac{1}{20}$) Dr. Porteous says, is a sedative to the stomach, liver and intestines, and favors the pouring out of the watery portions of the blood into the intestines. Small doses increase the secretions, large doses arrest them. Tablet triturates, each containing gr. $\frac{1}{20}$, prove useful in derangement of the alimentary tract in children often due to torpid liver. One must be given every half-hour till six or eight have been taken.

Opium given in small (gr. $\frac{1}{8}$) repeated doses, contrary to general teachings, *increases* secretions—*e. g.*, ovarian or other reflex pain which interferes with secretion and causes constipation is undoubtedly relieved by them. By them pain is relieved to such an extent that the secretions are re-established and purgation is the result. If given in like doses in bronchitis, where there is great dryness and burning pain with every cough, after several small doses secretion will take place and the raw feeling relieved.

Ten drops of nux vomica in a wineglassful of water, of which one teaspoonful is given every ten minutes for one hour, then every hour, has proved beneficial in the only case of vomiting of pregnancy in which Dr. Porteous tried it. The stimulating effects are not only felt upon the terminal filaments of the pneumogastric, but this action is carried to the liver, and extends to the entire nervous system, and as long as there are no astringents given to arrest peristalsis, the bile is carried downwards, and the vomiting ceases. In typhoid fever, when it is lingering and vitality is at a low ebb, it proves useful given of same strength as mentioned above, only every hour during day, and every two hours during night.

Nitro-glycerine has been in much favor for some time. Dr. Porteous has found it useful in one-drop doses of a one per cent. solution every five minutes during a paroxysm of asthma. If given in tablet form the tablet should be dissolved in the mouth before swallowing.

Chinese Treatment of Diphtheria.

The *Lancet*, November 22, 1890, says that a popular remedy for diphtheria, which has been employed in China for over 300

years, recently formed the subject of a communication by M. Lecerf to the Société de Médecine Pratique of Paris. The treatment consists of blowing a powder into the throat, using a decoction of plants as a gargle and drink, and the employment of certain hygienic measures. The powder is called *sin-seh*, and it appears to consist essentially of borax, camphor, powdered pearls, cinnabar, acetate of copper and charcoal, the percentage of borax and camphor being respectively 42.5 and 12. From twenty to thirty centigrams of this powder are blown through a paper tube every two hours. The decoction is difficult to imitate, as it is made from the following: roots of the coptis teeta (Scutellaria viscidula), Hanax quinquefolium or ginseng and Platycodon grand; flowers of Caprifolium chinense, fruit of the Uvularia cirrhosa, bark of Pterocarpus flavus, Capanus flavus root, and Glycyrrhiza glabra. About fifty grams of each are boiled in a pint of water until it is reduced to 200 cubic centigrams. This is filtered, allowed to cool and given in three doses in the twenty-four hours. The regimen enjoins the avoidance of ice, cold drinks, sugar and fatty matters and fruits, but allows at first boiled rice, eggs and salt fish, and later boiled chicken and bread. A large number of cases are said to be cured in three days, but the evidence on which they are termed diphtheritic is by no means conclusive.

Tuberculous Milk and Diseased Udders.

Dr. B. Bang, of Copenhagen, in the *Münchener med. Wochenschrift*, October 14, 1890, gives an account of his investigations undertaken to determine whether or not milk from tuberculous cows, but cows with healthy udders, is virulent. Observations made in the Copenhagen slaughter-house indicate that only a little over one per cent. of tuberculous cows have pronounced tuberculous udders. It is important, therefore, to determine whether the milk of tuberculous cows with healthy udders contains bacilli and is capable of transmitting the disease. Bang's first studies, made in 1884, led him to decide this question in the negative. In 1888, Bang made experiments with the milk of twenty-eight cows, nearly all tuberculous in a high degree, but with healthy udders. Forty-eight rabbits were subjected to intraperitoneal inoculation, and of the whole number only two became affected with the disease. The results of Hirschberger, working in Bollinger's Institute, were very different. He inoculated guinea-pigs intraperitoneally with the milk from twenty different tuberculous cows, and found eleven of the guinea-pigs infected. As guinea-pigs are more susceptible of tuberculosis than rabbits, Bang determined to re-investigate the question and use guinea-pigs. Forty of these animals were inoculated with the milk of twenty-one cows. The cows furnishing the milk were in a high degree tuberculous. After furnishing the milk they were, some time later, slaughtered, and their organs sent to Bang for investigation. He was thus enabled to know with certainty the exact condition of the animals. The milk of seventeen of the cows was not virulent, while that of four proved to be virulent. In three of these four cows, there was disease of the udder of different degrees. In the fourth cow, no disease of the udder could be detected, but the animal had advanced tuberculosis of the lungs, pleura, mediastinal and mesenteric glands, liver and intestinal canal, and had *died* of the disease, whereas the other animals had been slaughtered. Moreover, the udder had suffered from a chronic inflammation with shrinkage. The appearance was not that of tuberculosis, but as the tissue was not examined under the microscope tuberculosis could not be excluded absolutely even in this case.

The result of Bang's investigations appears to prove that the milk of tuberculous cows is virulent (by inoculation) only when there is at the same time disease of the udders.

Irregular Typhoid Fever Rash.

The *New York Medical Journal*, December 6, 1890, quotes Dr. R. L. MacDonnell as pointing out in a clinical lecture, in the *Montreal Medical Journal* for November, some atypical conditions of the skin among his cases at the General Hospital. The number of patients with the disease—seven men and five women—was somewhat larger than usual at this season of the year, but the type of the disease has, for the most part, been a mild one. Unilateral sweating was noticed in the case of the strong young Englishman who had a fairly severe attack of the fever. On the day of his admission

the one-sided sweating was well marked, but it had disappeared three days later. In one case a pale scarlatiniform rash was noted within a few hours after admission, confined to the neck and shoulders; it was of short duration. No medicines had been administered. In the case of a young girl, urticaria in distinct wheals manifested itself in the third week of an attack that had not been severe. In the case of a pregnant woman, who had a protracted attack of typhoid, there was jaundice lasting three days. In the case of a man who had a sharp attack, with extreme meteorism, for the relief of which turpentine stupes were used, pustules appeared upon the abdomen at the site of the typhoidal eruptive spots; in some of these small abscesses, containing from half a drachm to a drachm of pus, were formed.

This accident Dr. MacDonnell had noticed once before as a result of the use of turpentine stupes in fever. Four irregular forms of eruption in typhoid fever have been specified by Moore, of Dublin, such as erythema fugax, miliary eruptions, erythema simplex (seu scarlatinale), and urticaria. The scarlatiniform rash is most likely to show itself at the end of the first week or in the course of the third week, and when it appears early it is apt to give rise to diagnostic embarrassment, but the prodromes of scarlet fever are wanting, and the rash has been of a lighter color, less rough and punctiform than that of the exanthem; the rash is a blush rather than an eruption, and may be considered as a result of some disturbance of the peripheral vaso-motor system.

Alterability of Diuretine.

The *American Journal of Pharmacy*, December, 1890, says that diuretine is decomposed by all acids, even carbonic acid. Exposed to the air it becomes partially insoluble, making it necessary to treat it with caustic soda. Even in solutions, carbonic acid acts upon diuretine, and the mixtures become cloudy on account of the precipitation of theobromine. Not only weak acids, but such salts as the biborates, bicarbonates and dimetallic phosphates, decompose diuretine; hence, we cannot use it with fruit syrups or with soda bicarbonate. There is no advantage in giving theobromine transformed into diuretine, since, on reaching the stomach, it is decomposed by the gastric juice. It would be preferable to give theobromine in cachets or by enema.

Palatable Emulsion of Creasote.

The *Western Druggist*, November 15, 1890, gives the following for a palatable preparation of creasote, the taste of which is notoriously hard to disguise.

℞ Creasote . . . . . gtt. 16
Oil of clove . . . . . " 8
Oil of cinnamon . . . . . " 4
Oil of peppermint . . . . . " 4
Olive oil . . . . . fl. oz. 1
Acacia . . . . . fl. dr. 4
Water . . . . . " 6

Make an emulsion and complete the mixture by adding

℞ Glycerin . . . . . fl. dr. 4
Water . . . . enough to make " " 4

Each tablespoonful contains one drop of creasote. The aromatics may be increased.

The Tetrahydronaphthylamines.

Dr. R. Stern, in the *Archiv für pathologische Anatomie*, gives an account of some recent experiments made on animals with the tetrahydronaphthylamines. The preparation used was an aqueous solution administered hypodermically. An increase in temperature resulted in an hour, with dilatation of the pupil and general symptoms of poisoning. There was an increase in the quantity of urine voided, and in its nitrogenous and phosphatic constituents, the poison reaching its maximum effect on the second day, when the symptoms gradually subsided. The observer concluded that the changes in the urine were not those common to high temperature, but were consequent upon the specific poisonous action of the drug.—*New York Medical Journal*, November 29, 1890.

Challenge to a Fast.

Dr. H. S. Tanner, who fasted forty days, now lives near Clinton, Missouri. He has challenged Succi to sit down with him in Chicago during the World's Fair to test the matter in a ninety-days' fast on water only, or, if Succi prefers, let the fast continue from day to day till one or the other yields the contest.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

DIAGNOSTIC SIGNIFICANCE OF THE TUBERCLE BACILLUS.

Whatever views may be held in regard to the value of Koch's remedy for tuberculosis, there is certainly a very widespread conviction that the bacillus which he described as constantly present in tuberculosis is of great importance as an evidence of the nature of the morbid process. Careful and conscientious students of tuberculosis have doubted and have denied the significance attached to the bacillus by the followers of Koch; and the REPORTER has more than once indicated a feeling that the latter go further in some of their assumptions than the facts warrant. But fairness to our readers demands that we present what we believe are the views of the profession—even when they do not accord entirely with those of the Editor.

For this reason we call attention to a short communication in the *University Medical Magazine*, November, 1890, by Drs. Fussell and Kelly, of the University of Pennsylvania, urging the significance of the tubercle bacillus as diagnostic of tubercular phthisis.

In 1887 Dr. Fussell read a paper before the Philadelphia County Medical Society, based on the examination of the sputa of 100 cases of lung disease. The conclusions arrived at were: That the presence of tubercle bacilli in the sputa of any given case was undoubted proof of tuberculous phthisis, and that the continued absence of the organisms from the sputa of any given case was good, though not positive, proof of the absence of phthisis. These conclusions were confirmed by examination of the sputa of sixty-five cases in 1890.

In these sixty-five cases, forty-four patients had undoubted physical signs of phthisis, and tubercle bacilli were present in the sputa of all. Four had doubtful physical signs, and tubercle bacilli were found in the sputa of all. Eight had no physical signs of phthisis, and tubercle bacilli were absent from all. Nine had doubtful physical signs, and tubercle bacilli were absent from all.

The nine cases in which the signs were doubtful, and tubercle bacilli absent, are full of interest, but space prevents their extended notice. Two were cases of pneumonia, one of the apex in a boy with Pott's disease, where phthisis was feared, but who has entirely recovered. Another of the cases did not take the usual course of pneumonia, but has completely recovered. There was a case of pleurisy; one of anemia, with cough, etc. In all these cases it was a great relief to the physicians when repeated examinations failed to demonstrate bacilli.

That the ground, "absence of tubercle bacilli is good, though not positive, proof of absence of phthisis" is well taken is proved—Dr. Fussell thinks—by one of the cases he cites. This case is quoted in Dr. Fussell's article as one with doubtful signs,

absence of bacilli and recovery. In 1887 he had been under observation for one year, and seemed entirely well, but in 1889 he again came under observation, with marked consolidation of left apex, numerous bacilli in sputum and death early this year.

As the method of examining sputum for tubercle bacilli is simple, not requiring much technical knowledge, and but a moderately powerful microscope, it seems as if such examinations ought to be made in all cases in which there is suspicion of tuberculosis. By such examinations something would almost always be gained, and—if nothing else—a store of observation which might bring to agreement those who now do not agree on what is one of the most interesting pathological questions of the present day.

MYXŒDEMA RELIEVED BY GRAFTING WITH THE THYROID.

Myxœdema is a curious affection in which the features become broad, flattened and expressionless. The eyes appear too wide apart, the wings of the nose are thick, the lips large, the loose tissue below the eyes increased and folded, and heavy folds of connective tissue form under the jaws and in the neck. The tongue also undergoes enlargement and interferes with articulation, while the hands are broad and spade-like. The person affected gradually becomes less active mentally and physically, the prevailing mood being one of placid indifference and apathy.

Several varieties of myxœdema have been described: Myxœdema of adults (pachydermic cachexia of Charcot); operative myxœdema of Reverdin (cachexia strumipriva of Kocher); and idiocy with pachydermic cachexia of Bourneville and Bricon —the sporadic cretinism of English writers. The link which unites these varieties is absence of the thyroid body, or its disappearance as the result of disease or surgical operation. Kocher found that removal of the thyroid for goitre, which is so common in Switzerland, resulted in producing a condition very similar to cretinism in the adult; and Horsley produced a similar condition by removing the thyroid in monkeys. Following these experiments, Schiff went a step further by making the first graft of a thyroid. His purpose was to prove that the thyroid has chemical and hematopoietic functions independent of its position. He showed this by transplanting to the peritoneal cavities of several dogs, some time before doing thyroidectomy on them, portions of a thyroid from another dog. The result was satisfactory: the animals survived thyroidectomy without presenting the phenomena usually provoked in animals by ablation of the thyroid. Eiselsberg confirmed Schiff's experiments, employing cats instead of dogs, and adding the important observation that the death of the animal from thyroidectomy is prevented only when the graft of another portion of thyroid succeeds.

If the grafting of a portion of thyroid prevents the results of thyroidectomy in animals, why should it not prevent or overcome myxœdema in human beings? asked Horsley, in the *British Medical Journal*, February 8, 1890. Lannelongue, as described in an Editorial in the REPORTER, April 12, 1890, undertook to accomplish this, and it has been tried also by Bircher, Kocher and others. In *Le Mercredi Médical*, November 19, 1890, Merklen and Walther give a review of the cases in which grafting with the thyroid for myxœdema has been done, and report in detail a case of their own. The patient was a woman, forty-one years old, who had had myxœdema for ten years. Metrorrhagia preceded by ten years the development of myxœdema, and had never ceased since the occurrence of the latter. Walther, at the request of Merklen, transplanted one of the lobes of a thyroid from a sheep into the sub-mammary region on the right side of the patient. The operation was done so that only a few seconds elapsed between the removal of the

portion of thyroid from the sheep and its insertion into the patient.

The metrorrhagia from which the patient suffered ceased three days after the operation, and had not been reproduced up to the time of the report, seventy-two days subsequent to the operation. At the same time there was a remarkable improvement in the patient's myxœdema; the outward evidences of the disease became less conspicuous, speech was much more distinct, and the patient could walk easily and quickly about the ward, whereas several weeks before it had required fifteen minutes for her to make the tour of the ward.

The exact future of this operation cannot be predicted at present. It is perhaps a step in the right direction; and while those who may require it are unquestionably more numerous in Europe than in this country, there is no impropriety in calling attention to it here. One thing deserves mention before leaving the subject; in some of the cases in which grafting has been done, the transplanted thyroid has, after a time, atrophied, the symptoms of myxœdema have reappeared, and a second grafting has been necessary. In Merklen's case, also, the transplanted thyroid, when last examined, appeared to have diminished somewhat in volume. Perhaps later experience will avoid the disappearance of the graft by indicating a better seat for it.

THE GONOCOCCUS IN THE DIAGNOSIS OF VULVITIS.

Physicians are often in doubt whether a particular vaginal discharge is gonorrhœal or due to some other cause capable of provoking suppurative inflammation. When, in adults, the discharge has appeared suddenly, is purulent in character, and in its early stages has been associated with scalding pain on micturition, a hot and tender vagina with bright red points covering the mucous membrane, and with a red, velvety or granular os uteri, the probabilities are altogether in favor of gonorrhœa. And yet it is doubtful whether many men could be found willing to take the witness stand and declare positively, from the symptoms and appearances we have described, that the disease is gonorrhœa. The difficulty becomes still greater when the patient is not an adult but a child. Fortunately the cases of gonorrhœa in little girls are much less frequent in this country than they appear to be on the continent of Europe, where physicians to law courts have been put to it to find an infallible method of differentiating gonorrhœal vulvitis from that due to other causes.

The discovery of the so-called "gonococcus" by Neisser was hailed by many with enthusiasm. Supposing it to be the specific cause of gonorrhœa, then to find it in a suspicious discharge would be proof of the gonorrhœal character of the discharge. But it was scarcely discovered before assertions were made that it could be found in non-specific discharges, and that it could not be distinguished under the microscope from other bacteria, particularly diplococci. The latter conclusion is the one to which Vibert and Bordas have come. These writers have investigated, from a medico-legal point of view, the discharge present in the vulvitis of little girls, and declare, in *La Médecine Moderne*, November 13, 1890, that microscopic examination of such discharge never enables an expert to affirm that a particular vulvitis is or is not gonorrhœal. They find the gonococcus practically indistinguishable from the diplococcus—both bacteria, they say, have the same form and dimensions, the same arrangement in masses and heaps, and not in chains, and they stain alike and are alike deprived of their stain by alcohol.

It not infrequently happens that men are accused of having committed rape upon little girls, and sometimes vulvitis is adduced as one of the evidences of the violation. A vulvitis, however, has been found in a violated child although the person guilty of the rape was free from any evidences of urethral

disease. It would seem to be impossible, therefore, in the present state of our knowledge of the bacteriology of gonorrhœa, to base upon it a diagnosis sufficiently positive to warrant a judgment by the court in a criminal suit. No doubt this difficulty will be overcome by and by, and perhaps by cultivation the gonococcus can be distinguished from the diplococcus. But just now the conclusion seems to be that our methods of detecting the gonococcus are not precise enough for medico-legal purposes.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE DAUGHTER—HER HEALTH, EDUCATION AND WEDLOCK. By William M. Capp, M. D. 5½x7 inches, pp. viii, 144. Philadelphia and London: F. A. Davis, 1891. Price, $1.00.

Dr. Capp's little book is written in an attractive style, and contains a great deal of what he fitly calls "homely suggestions for mothers and daughters." The subject of the book is the development and training of young women for the position and duties peculiar to their sex. It is decidedly pleasant to see a book of this sort, which—in the present fever to make women like men—treats of them as women solely. Dr. Capp gives such advice as, we think, will be welcomed and approved by womanly women, and of a sort which, well pondered and wisely followed, will tend to increase the number of women capable of being good and loved wives and mothers. We commend his book to the attention of the readers of the Reporter, and believe it would be a help to most thoughtful parents who have daughters to train.

A MANUAL OF THE PRACTICE OF MEDICINE. By Frederick Taylor, M. D., F. R. C. P., Physician to, and Lecturer on Medicine at Guy's Hospital, etc. 8vo, pp. 877. With illustrations. Philadelphia: P. Blakiston, Son & Co., 1890. Price, $4.00.

Dr. Taylor has undertaken to write a short yet complete account of the present state of medical practice. It cannot be denied that such an undertaking demands great courage when one considers the vast extent of the field to be covered. Only a man of large experience, and one accustomed, through teaching, to concise and exact methods of thought and expression, could accomplish the task; but Dr. Taylor has succeeded admirably.

After a short but pithy introduction, the author takes up specific infectious diseases, including in this classification, influenza, syphilis and tuberculosis. The following two hundred pages are given to diseases of the nervous system. Then follow in succession accounts of the diseases of the organs of respiration and of circulation, diseases of digestion, diseases of the ductless glands, lymphatic system and blood, diseases of the urinary organs, diseases of the organs of locomotion, and, finally, diseases of the skin.

The author is aware that in treating of diabetes under diseases of the kidneys, and of rheumatism and rickets under diseases of the organs of locomotion, he lays himself open to criticism. He has placed them where he has for convenience and provisionally, until a better understanding of their pathology makes a proper classification possible.

We have already spoken in warm praise of the book, and have only to add that it is just the one to put into the hands of a student who wishes to read up a subject while he is listening to lectures on practice; it is full enough to be clear without being full enough to confuse.

A COMPEND OF HUMAN ANATOMY, INCLUDING THE ANATOMY OF THE VISCERA. By Samuel O. L. Potter, M. A., M. D., Professor of Theory and Practice of Medicine in the Cooper Medical College of San Francisco, etc. Small 8vo, pp. 315. Fifth edition, revised and enlarged. Philadelphia: P. Blakiston, Son & Co., 1890. Price, $1.00.

The present volume includes in one the author's compends on "Human Anatomy" and "Visceral Anatomy" which were originally published in separate parts. The text as first published, has been somewhat amplified, and the number of wood-cuts increased by eighteen, so that now the whole number of cuts is one hundred and seventeen. In an appendix are given sixteen plates representing the nerves and arteries.

The book as it stands is a very complete compend of anatomy; indeed, if it were not for the arrangement, one might be justified in speaking of it as a small treatise on anatomy. We can recommend it to students, and to any of our readers who desire such a book.

Correspondence.

Work in the Woman's Hospital of Philadelphia.

To the Editor.

Sir: Apropos of the excellent Editorial entitled "The Modern View of Diseases of the Uterus" in the Medical and Surgical Reportfr December 13, 1890, it may be of interest to your readers to learn something of the past year's work in gynecology at the Woman's Hospital of Philadelphia—not the "Woman's Medical College Hospital" as is often stated. The "Woman's Medical College of Pennsylvania" and the "Woman's Hospital of Philadelphia" are distinct institutions with entirely separate management, although with a common interest.

A review of the work in the Hospital for the past year shows that the tendencies of modern thought and the refinements of surgical science have materially affected its methods of procedure. Since aseptic sur-

gery has robbed the knife of its terrors, and an exploratory incision may be made, as every surgeon knows, without costing the patient the loss of even a drachm of blood, it has not been thought necessary to subject patients to a long-continued treatment in the dark, with palliative measures, before resorting to more radical means for discovering the true nature of their maladies, and the possibility of relief. Our proportion of abdominal sections is for this reason larger than that of previous years, although not really so large, as yet, as the number and character of the cases applying to us for relief would warrant.

Of 668 patients treated in the house, nearly 500 were gynecological cases, while 1,948 cases were treated during the year at the gynecological clinic alone. Of 56 laparotomies performed, 48 were for disease of pelvic origin. Six of these were ovariotomies; four were hysterectomies; thirty-one were for the removal of diseased uterine appendages; four for the breaking up of adhesions and correction of uterine displacements; one for the removal of a dermoid cyst; two for multiple puncture of cystic ovaries. Four deaths occurred among the number; three of them in cases of suppurating ovarian cystomata—in all of which general sepsis had existed prior to operation, from absorption of fetid pus which had long been incarcerated in the pelvis. The fourth death occurred a week after the performance of a successful hysterectomy in a patient with frequent severe hemorrhages from a bleeding fibroid. The patient had been thus bleeding for two years, and her anemia was extreme. Not an ounce of blood was lost during the operation. An autopsy showed a perfect condition of the abdomen, wound and stump. The heart was very pale with flabby walls, a small clot was found in one of the chambers. The stomach was somewhat enlarged and distended with flatus. The supposition was that death occurred from embolus, or interference with the action of a very weak heart caused by the pressure of the distended stomach. The case had been afebrile throughout. Death occurred within half an hour of the patient's complaint of pain in the region of her heart. How striking a comment do these four cases offer to the evils of delay in resort to operative procedure!

Among the cases of simple amputation of the uterine appendages, no deaths occurred. The results in the cases surviving operation have been, as a rule, most gratifying. In twenty-five cases of successful abdominal section this year, reported by me in the November number of the *Annals of Gynecology and Pediatry*, the results here in every case surpassed my expectations. All the cases in which pain existed have been entirely relieved, and the general condition of the patient has been greatly improved. I speak of this here, as reference was made to some of these cases in an article in the REPORTER, August 16, 1890, when it was much too early after operation to make results worth recording. In an experience with about one hundred and twenty-five cases of abdominal section which have come under my immediate charge, I have always found a logical explanation where the operation failed to meet expectations. Either the operation had been undertaken too late to afford more than a forlorn hope, or the complications resulting from repeated attacks of inflammation had been found to be insurmountable, resulting in a partial and unsatisfactory removal of diseased structures, the remains of which continued to serve as a source of local irritation. Surgery must sometimes undertake desperate cases, and it loses prestige thereby. Of minor operations, 64 perineorrhaphies were performed and 30 trachelorrhaphies, etc., amounting in sum total to 155. Operations in general surgery and those performed in our obstetrical wards bring the number of house operations up to 306. The addition of the operations performed in the various departments of our Dispensary work makes the total number 731.

Electricity has been but little employed in the management of our cases during the past year; and this because of my honest conviction that, as yet, the laws governing the action of this subtle agent are too ill-defined to render its use safe in conditions of disease affecting the delicate structures to be found in the pelvis.

Five years' personal trial of the methods of electricity as advised by its advanced teachers, has led me to this decision. Although, as resident in the Hospital in 1882, I was taught to employ electricity to some extent for the relief of pain, the control of hemorrhage, etc., it was not until 1885 that the Apostoli methods were fully introduced here. It was then that one of our physicians visiting Apostoli's clinic in Paris and studying his methods, brought home with her various forms of electrodes

and appliances as recommended by him. The Managers of the Hospital generously supplied us with an excellent and expensive battery capable of giving a current of 150–200 milliampères, and imported a galvanometer said to be of the best make. Since then the literature of the subject has been carefully followed and every effort made to bring about the conditions which would favor success. The Apostoli electrodes have been used, the Apostoli clay-pads employed and Apostoli rules followed. Intra-uterine applications have never been relegated to assistants, excepting under my direct supervision and instruction.

A pupil of Apostoli, one of Dr. Chas. K. Mills, and one of Dr. Massey, who have at different times, had charge of our electrical clinic, may have occasionally given intra-uterine applications to dispensary patients; but as a rule, such applications have been confined entirely to house patients. For many months no intra-uterine applications have been permitted to be employed in dispensary work. The result has been that in our hands electricity has proved an uncertain, unsatisfactory and at times a treacherous agent. Among a large number of cases treated, I cannot recall one we could consider permanently cured by its means. Relief of pain for variable periods of time with the occasional control of hemorrhage, has been obtained while the patients continued under treatment. Repeated attacks of inflammation have occurred, notwithstanding precautions. These, taken in time were readily suppressed; but that they left their impression upon the peritoneum was very evident in several instances where a final resort was had to laparotomy. A special proneness to the occurrence of omental adhesions I have found in many cases. One case of fibroid will perhaps serve as an illustration. The patient was admitted to the Hospital in February, 1886, when the record states her condition to have been as follows: "A large fibroid mass, *very movable*, apparently interstitial, fills the pelvic brim and extends to one inch below the umbilicus; cervix effaced."

From February 19 to September 7, 1886, the patient was treated by galvano-puncture, alternating with intra-uterine applications, according to Apostoli's method. After her last treatment on September 6, 1886, I find the following entry: "Tumor about the same size as when patient came in, the severe paroxysmal pains from which she has suffered continue to recur." On June 16, 1887, the patient returned to us. The tumor was found to be wider laterally than it had been before, and the amount of pressure it exercised brought the body of the uterus down in the anterior *cul-de-sac* to within 1½ inches of the vulva. The patient remained with us under electrical treatment until August 26, 1887, when she was discharged, materially in the same condition as when she came. She returned for the third time to the Hospital on December 31, 1887, when she was seen by Dr. Granville Bantock, of the Samaritan Hospital, London. Dr. Bantock thought the case unfavorable for operation, because of the fixation and lateral developments of the tumor. Treatment with electricity was again begun, but it was continued only about one week, domestic difficulties calling the patient home. Her extreme distress, and the fact that the tumor was greatly increasing in size, so that it now reached almost to the diaphragm, led her to return to us for the fourth time on December 13, 1888. She begged to have an attempt made for its removal. An exploratory incision was performed on December 29, 1888. The tumor and all the contents of the abdomen were a conglomerate mass of adhesions, so that removal was an utter impossibility. A few parietal adhesions were broken up and the abdomen was closed.

This sad life was terminated by death from sepsis due to breaking down of the tumor early in the spring of 1890, after the most intense suffering.

Since the discovery of truth should be the aim of all earnest workers, and the free discussion of medical topics can alone stimulate the intellectual processes essential to the development of science, I trust the expression of my views concerning electricity will not be regarded as a personal attack upon any of your readers who may hold different opinions of its claims.

Experts in electricity will indeed confer a blessing on humanity if they can prove that by the use of this agent disorganized tissue can be restored to its original conditions and functions. Reconstruction is to be preferred to ablation. Ordinary conditions of beginning inflammation are not those which baffle the skill of the gynecologist. The vicious conditions of life and thought which render pelvic disease so prevalent in this day, result in maladies so various and complicated that human skill is appalled at the difficult task of undertaking their cure.

The wise control of preventive medicine may in time lead to the extinction of such maladies; but as they exist, the important question is: How shall they be managed?

It is a difficult thing for any physician to advise a patient to shut herself out from the possibility of experiencing the joys of motherhood, and it can only be done when one feels the conviction that disease has already rendered *safe motherhood* an impossibility to her.

In our Hospital, where we are accustomed to explain to the patient and her friends the full nature of any operation with its results, and obtain from them a written statement as to their desire to have the procedure carried out, before it is attempted, I have yet to find the man who has not been willing to sacrifice every other consideration to his wife's good. It has oftener been the woman who has hesitated or deliberately chosen a life of suffering with a possibility perhaps of sudden death, rather than accept the alternative of a childless life.

Very truly,
ANNA M. FULLERTON, M. D.,
Physician in Charge.
Woman's Hospital,
Philadelphia.

Powder Blower.

TO THE EDITOR.

Sir: In January, 1889, I read a paper on Diphtheria before the Practitioners' Club of this city, which was published in part by you in your issue of November 23, 1889. In this paper I strongly advocated the use of sulphur in diphtheria and tonsillitis, and quoted authorities in support of its claim to usefulness for hundreds of years.

After reading the paper I presented to the society an instrument I had constructed for examining the throat and introducing sulphur and other medicated powders, to take the place of quills, cut-off catheters, glass tubes, putty blowers, rolled-up paper, and the many troublesome makeshifts, that have always vexed the souls of doctors and nurses. It was accepted as a happy solution of the question, and has since been used with much satisfaction, especially as it has been found a great improvement on other tongue spatula for throat inspection. It consists of a small tube four or five inches long, with a spoon attached to it. The spoon is bent on itself to pass over the tongue and shove it forward, and is highly polished to illuminate the parts, and is to be washed in boiling water to prevent contagion. The powder is to be blown through the tube by the mouth, or any powder blower.

A year's experience has demonstrated its usefulness, and also shown its possible needs. To make it complete, I have now added a rubber ball, with a scoop attachment, which makes it a firm continuous instrument to be used with one hand. And to make it still more complete, a tube with a bulb is to be attached to the ball and scoop, for nasal insufflation or irrigation.

These attachments also greatly enlarge its use; and since aristol has given such an impetus to powder medication of the nose and throat, the instrument seems to promise usefulness in the treatment of acute or chronic catarrh, as well as of diphtheria and tonsillitis. But the little illustration sent—which please have your printer place in your advertisement columns—will tell the story better than pages of fine print.

Yours truly,
J. D. OSBORNE, M. D.
1034 Broad Street,
Newark, N. J.

QUESTIONS AND ANSWERS.

[In this department will be published questions on any medical subject by readers of the REPORTER, and answers by the EDITOR or by other readers.]

Difficulty in Micturition.

DR. GILES LUCAS, of Alma, Ark., writes for information about the following case. Mrs. J., seventy years old, the mother of two children, of nervous temperament, and rather active for one of her age, consulted him in May for the relief of the following trouble. She said that for the last ten years she had been troubled at intervals of from ten days to several weeks with spells of painful and frequent micturition. The spells lasted from two to ten days. During the spells she suffered constantly with throbbing pain about the neck of the bladder. When she voided urine—which she was compelled to do every fifteen or twenty minutes—the pain was almost unbearable.

On examination, Dr. Lucas found that the urethra was very sensitive about the sphincter of the bladder, and there was some resistance to the passage of the catheter. There was no morbid growth or other abnormality. The introduction of

the catheter gave her so much relief, that she frequently calls on him to repeat it. The introduction of the catheter, or sound, and the local use of morphia, are the only means that relieve her. Her urine is normal. This case has given Dr. Lucas great anxiety, and any information concerning it will be gladly received.

NOTES AND COMMENTS.

Depopulation of France.

It is somewhat startling to find that the depopulation of France is becoming a common subject of discussion among the *savants* of that country. The phrase is perhaps somewhat stronger than the circumstances of the case warrant, the fact being that the population of France is simply stationary. Still it is a striking and significant circumstance that while the population of all the other great European nations is steadily and rapidly advancing, that of France remains at a standstill. On economic grounds this arrest of increase in number might seem not altogether an unmixed evil, inasmuch as it should tend to diminish over-competition, and to ease the already excessive struggle for existence among the lower classes; but an impression widely prevails that given a fairly normal and healthy social condition a growth of population is a natural result, and that a stationary or declining population is an index of some grave disorder of the body politic. We cannot adequately discuss this large and difficult question, but our French neighbors evidently think that something is amiss, and are looking around for the cause and for its remedy. Probably the causes are numerous and complex. Social habits may account for a good deal. The French custom of subdividing land and of providing a dowry for girls offers an obvious motive for keeping down the number of children. Where, as in the west of Ireland, the peasantry have a cheap food supply, and are constitutionally averse to thrift, large families are the rule; but in France thrift is a virtue carried almost to excess, and the obligation of the parents to provide for each new accession to the family is clearly recognized. Moral causes have been supposed to play a large part in the arrest of the population of France, and we are far from under-estimating their importance, but this is a difficult and delicate problem, on which it would be rash to dogmatize without the most ample evidence.

While some of the causes of the phenomenon under discussion may be obscure and remote, others lie under our eyes, and cannot be too carefully scrutinized or too frankly acknowledged. In a recent address before the Académie de Médicine, Dr. Brouardel, drew attention to the abnormal mortality from small-pox and typhoid fever which prevails in France. He points out that while Germany loses only 110 persons per annum from small-pox, France actually loses 14,000. Dr. Brouardel attributes this astounding difference to the rigid way in which vaccination is enforced in Germany, and to the carelessness of his own countrymen in this matter. Statistics show that in 1865, when vaccination was not obligatory in Prussia, the mortality was 27 per 100,000 inhabitants. After vaccination was enforced the mortality fell in 1874 to 3.60 per 100,000, and in 1886 to 0.049. At the present time the mortality from this cause in France is 43 per 100,000. We make a present of these figures of Dr. Brouardel to the Royal Commission on Vaccination.

As regards typhoid fever the deaths due to this disease in France amount to 23,000 per annum. Dr. Brouardel gives a great variety of statistics to show that the liability to typhoid is in direct proportion to the imperfections in the water-supply, and that in proportion as a sufficient supply of pure water is provided, typhoid abates. Thus, at Vienne the typhoid mortality was 200 per 100,000 while the inhabitants drank surface, hence often polluted, water; but this mortality fell to 10 per 100,000 on a thoroughly good supply being obtained. At Angoulême the introduction of a new supply of pure water reduced the number of cases of typhoid in the proportion of 0.063 to 18. At Amiens, among the military population, the typhoid mortality fell from 111 per 10,000 to 7 when a pure supply of water was secured by artesian wells. At Rennes the inhabitants formerly drank from contaminated wells, with the result that typhoid fever was always endemic. The introduction of pure water reduced the deaths from typhoid among the military population from 43 per 10,000 to 2. Investigations carried out at Besançon, Tours, Carcassonne, Paris and Bordeaux entirely corroborate the above striking figures. Typhoid fever is responsible for the deaths of 1 soldier in 335 in France, or 298 per 100,000, and this in time

of peace. In war its ravages are even far greater. Thus the expeditionary corps to Tunis in 1881, consisting of 20,000 men, had 4,500 cases of typhoid with 884 deaths.

Dr. Brouardel concludes by affirming that if vaccination and re-vaccination were rendered obligatory in France, and if the towns were everywhere supplied with pure water, the country would save from 25,000 to 30,000 lives annually, and these, for the most part, of young persons of marriageable age. He therefore proposes to the Academy to adopt the following conclusions: "That the sanitary law in preparation ought to render vaccination obligatory; it ought to furnish sufficient authority to the municipalities, or in their default the Prefect or the Government, to secure the public health against the dangers which result from using polluted water."

In the discussion which followed Dr. Brouardel's communication many important points were elicited. One speaker drew attention to the evils which arose from cheap lodging-houses. Another insisted upon the superiority of supplying pure water to any methods of filtration. At Angoulême filtration was tried with some advantage, but the provision of a pure supply proved much more successful.

We may learn something from the anxieties of our neighbors. If the outcry against compulsory vaccination now prevailing in some quarters in this country should unhappily effect any slackening in our vigilance in this matter, we shall surely pay the penalty in a heavier mortality from one of the most loathsome of diseases. The example of Germany in this matter is admirable and cannot be too widely known or too carefully followed. The provision of an absolutely pure supply of water to our large cities is a much more difficult problem than the thorough enforcement of vaccination, but it is at least the ideal towards which our efforts must be directed. It is an immense gain to know positively both the source of danger and the means of averting it, and we must never rest content so long as an acknowledged source of disease, misery and national weakness is permitted to exist in our midst.—*Lancet*, December 20, 1890.

Apomorphia.

In the *Medical Record*, December 6, 1890, Dr. J. S. Horsley, of West Point, Ga., has an article, in which he advocates the use of apomorphia to control spasmodic seizures of various kinds. He describes the results which followed its administration in four cases under his care, in all but one of which it is probable (in our opinion) that the effect was wholly due to the relief produced by vomiting.

However, we may quote what Dr. Horsley says, so that he may speak for himself. He says he could mention other cases illustrative of the beneficial effects of apomorphia, but he thinks the cases cited sufficient to present this new use of the remedy; that of preventing and controlling convulsions, and other motor disturbances. He has seen so little written on the uses of apomorphia and that usually in relation to its action as an emetic, that he concludes that it is not appreciated at its full value by the profession. He has not been able to find any report of the use of apomorphia in motor disturbances for other than the relief to be expected from emptying the stomach, except a case in which a German physician succeeded in cutting short epileptic attacks by the subcutaneous injection of apomorphia during the aura; while Dr. Edward Cockrell, of England, is reported to have successfully treated infantile convulsions by its use. It is not stated whether the convulsions resulted from gastric disturbance or not; but as that is the usual cause of convulsions in children, we may suppose that its emetic action was sought in this case. The remedy has hitherto been used principally for its emetic action, and this was Dr. Horsley's object in using it, until he accidentally found that it controlled the spasms produced by strychnine poisoning. Since that time he has been using apomorphia for all convulsions, and in no case has he yet been disappointed as to the result. He calls attention to the fact that it arrests or prevents spasms and other motor disturbances. From the results obtained from its use in his limited experience, he confidently expects it to control any spasm not caused by lesion of the brain or spinal cord.

It is quite probable that this remedy will be of service in controlling the spasms during an attack of tetanus or rabies. He has had no opportunity of testing its value in either case, but from the analogy existing between these affections and poisoning by strychnine, Dr. Horsley thinks we might reasonably give it a trial in these affections.

Pathological Anatomy and Pathogeny of Ecthyma.

Leloir and Vidal discuss the pathological anatomy and pathogeny of ecthyma at considerable length in the *Gazette Hebdomadaire*, November 15, 1890. They define ecthyma as an auto-inoculable and inoculable disease of the skin, characterized by large, round, globular pustules with a hard base, the pustules being succeeded by brownish crusts which leave on falling off more or less apparent cicatrices. Vidal believes that he has to a great degree contributed towards establishing the fact that ecthyma is a disease by itself, distinct from impetigo and other diseases. It always leaves an indelible trace, a cicatrix more or less depressed and apparent according as the chorion has been more or less injured. Leloir and Vidal have inoculated skin and mucous membranes with the pus from various tissues and inflammations and have invariably failed to produce ecthyma. On the other hand, the pus from true ecthyma, when inoculated or auto-inoculated, reproduces a characteristic ecthymatous pustule, which reaches its height on the fourth day; and, from this one, another series of pustules can be obtained, up to five successive generations. Exceptionally a sixth generation can be obtained, but usually the reproductive power lessens with each successive crop.

Simple ecthyma usually runs an acute course. Its duration, which is ordinarily a few weeks, can be abridged by treatment to a few days. If uncared for, and in debilitated persons or such as are addicted to alcohol, it may pass to a chronic state, either by successive auto-inoculations which perpetuate the duration, or by giving place to chronic ulcers.

If it appears probable that in a certain number of cases at least ecthyma is caused by the entrance of micro-organisms into the epidermis, this has not yet been demonstrated absolutely. Up to the present time no one, as far as Leloir and Vidal know, has succeeded in producing ecthyma by inoculating cultures more or less pure of its micro-organisms. Possibly the alkaloids produced by the organisms are also necessary. But the question of causation is more complex than it seems at first sight, for lesions having all the characteristics of ecthyma have been seen to follow affections of the nervous system. It is also certain that in a number of cases ecthyma is produced by toxic chemical agents coming from without, and, in certain cases, perhaps, secreted by the organism and eliminated by the skin; but Leloir and Vidal do not say whether or not they consider these agents sufficient to provoke suppuration in the absence of micro-organisms.

Influence of Tobacco-Smoking on the Stomach.

In the *Vratch*, No. 48, 1890, p. 1091, Dr. N. I. Jdan-Püshkin, of St. Petersburg, writes that in order to study the action of tobacco-smoking on the gastric functions, he has undertaken a course of experiments on seven healthy young men, aged from 17 to 27, all of them being habitually non-smokers. In each instance, the experiment lasted nine days, being divided into three equally long periods, during the second of which the subject was smoking 25 cigarettes a day. Briefly told, the following conclusions were reached by the author. 1. Tobacco-smoking increases the secretion of the gastric juices, but at the same time lowers its general acidity. 2. It also decreases the proportion of free hydrochloric acid in the juice, and that in a direct ratio to the fall of the general acidity. 3. The diminution of the proportion of free hydrochloric acid, as can be expected, leads to weakening of the digestive powers of the juice. 4. Tobacco-smoking retards the secretion of the rennet-ferment (Hammarsten's *Lab-ferment*), as shown by a marked retardation of curdling of milk after the addition of the juice. 5. All the changes prove to persist for a couple of days after discontinuing smoking. 6. The motor and absorptive powers of the stomach, however, are somewhat increased by the use of tobacco [meanwhile Drs. Tcüdnovsky, Grammatchikoff, and Ossendowski have found that smoking retards the passage of food from the stomach into the duodenum.—REPORTER]. 7. Smoking does not manifest any influence on the acidity of the urine. On the whole, the author seems to entertain rather unfavorable views in regard to tobacco-smoking. Amongst other things, he points out that the weed depresses the assimilation of proteids (as Grammatchikoff's and Ossendowski's experiments have shown), raises the bodily temperature and accelerates the pulse (Prof. I. V. Troitzky), causes sometimes dyspepsia, constipation, meteorism and other gastro-intes-

tinal disturbances (Treumann, Dubois), produces cardiac neuroses, failure of vision, etc., etc.

Micro-Organisms in Cities.

Professor Tarnier in his course of lectures on obstetrics, in 1890, referred to M. Miquel's researches on the relative abundance of micro-organisms in different places. One to the cubic meter of air is the proportion at the top of a high mountain. In the Parc de Montsouris in the south of Paris, M. Miquel found 480 micro-organisms to the cubic meter of air, whilst in the Rue de Rivoli the proportion was 3,480. In a new room in the Rue Censier he found 4,500 to the cubic meter; more, that is to say, than in the centre of Paris in the open air. In a room in the Rue Monge, he counted 36,000, in the Hotel Dieu 40,000, and in the Pitié, an older hospital, 319,000 micro-organisms to the cubic meter. At the Observatory Montsouris, 650,000 microbes were found in a gram (15 grains) of dust; in the room in the Rue Monge the amount was 2,100,000. In the hospitals the proportion was so high that counting the number of microbes in a whole gram of dust was found to be impossible. The dust is the great conveyor of micro-organisms. At 2 A. M., when a city is most quiet, the fewest germs are to be found in the air; at 8 A. M. the industry of domestic servants and dustmen has already made the air to teem with germs. At 2 P. M. the proportion has again greatly fallen; at 7 P. M. it is once more high, for many houses are being "tidied up"; besides sundry kitchen operations are unhygienic. Thus the "small hours" unfavorable in many respects to patients hovering between life and death, are the least septic of the twenty-four. The day proportions indicate that household duties cause more septic diffusion than is excited by traffic and industry.—*British Medical Journal,* November 15, 1890.

"Antifebrinization" in Typhoid Fever and Consumption.

According to the *Wiener med. Presse,* October 19, 1890, Dr. Favrat has made numerous trials in the clinic of Prof. Sahli, of Berne, of "antifebrinization" with minute doses of antifebrin. He communicates a paper on the subject to the *Archiv für klin. Medicin,* Bd. 46, and recommends the practice in typhoid fever and consumption. He says that antifebrin in doses of from five to ten centigrammes (¾ of a grain to one and one-half grains), is well borne by patients with typhoid fever and phthisis. It produces a gentle antipyresis which is grateful to the patient, and, administered in the way just mentioned, to a great degree the evils of large doses are avoided. In children it is proper to begin in all cases with doses of one-sixth or one-third of a grain. In typhoid fever the administration of the minute doses in the way described causes a lowering of the fever and an improvement in the subjective sensations of the patient. The hectic fever of phthisical patients is also overcome and the patient made more comfortable. The remedy acts better the higher the fever. In phthisical patients a dose of from five-sixths of a grain to one and one-half grains sometimes suffices to depress the temperature more than three and three-fifths degrees Fahr. In cases in which antipyresis is long continued the patient becomes gradually accustomed to doses that were at first effective. It is then best not to increase the dose but to stop the remedy for a time or to substitute another for it. Later on the doses used at first will again be found effective.

Abortion for Vomiting of Pregnancy.

Dr. Henry Fruitnight, of New York, in the *American Journal of Obstetrics,* December, 1890, gives a review of the subject of inducing abortion for the vomiting of pregnancy, with description of cases, and says:

"From these histories the following deductions can be drawn: First, that when nature spontaneously interrupts the course of pregnancy by the occurrence of premature delivery, the patient recovers. Secondly, that when pregnancy is allowed to proceed uninterruptedly to its natural termination, an almost certain fatal result will befall both mother and child. Thirdly, that when the patient, the victim of grave vomiting, is permitted to advance too far in the course of pregnancy before the operation of induction of premature labor is done, the probability is that she will not be able to resist the added shock of the operation in her already debilitated condition, but will succumb. Fourthly, that when the operation is done *secundum artem,* at the properly elected period of time, the probability is that we will save the life of the mother in

any event, and in many instances, in proper cases, the lives of both mother and child. And upon these deductions the following conclusion is based: When hyperemesis seriously and dangerously affects the health of the woman, and does not respond to a judicious and systematic course of treatment with all known and approved remedies, then the operation of the induction of premature labor in such cases is at once justifiable and the only thing left for us to do."

Women and Women Physicians in India.

The *Indian Medical Gazette*, November, 1890, says that the native women frequenting the Balrampur Hospital, Lucknow, are so much behind the age that they elect the services of male in preference to female doctors. This is what Dr. Rice, the Inspector-General of Civil Hospitals, says on the subject:—"With regard to the 934 major surgical operations done in the female hospitals, it is but right that I should state that the large majority of them have been done by the Civil or Assistant Surgeons, and this is right generally. The greater part of them are of a nature unconnected with the sex of the sufferer. I have myself seen women insist that the operations should be done by the male doctor: and not only that, but that they should be done in the male hospital, so as to make sure of his operating. The principle of management is that, as far as we are concerned, every women shall be left a free agent in the selection of the particular division of the hospital in which she shall be treated."

Hydrate of Amyl in Epilepsy.

In a recent number of the *Therapeutische Monatshefte* the experience of the use of this drug in doses of from five to eight grams per day, in the cases of seven epileptics, is related. Two of the patients, previously subject to from nine to eleven attacks per month, remained free from them as long as the drug was taken; in a third improvement seemed to take place at first; in the remaining four no appreciable effect was produced on the number or severity of the fits. In all seven there was produced by the drug a great desire for sleep, and after it was left off the rest was disturbed; and in cases in which previously sleep had been sound and undisturbed, it now became light and broken. In three patients, also, after the medicine was left off, there were for several days series of fits, although those patients previously had not, as a rule, had more than one or two convulsions in the day.

A Laryngological Curiosity.

The *Medical Press*, December 3, 1890, states that at a recent meeting of laryngologists in London, Mr. Lennox Browne described the case of a middle-aged woman who was sent to him from the provinces for the purpose of deciding whether her malady was laryngeal cancer or phthisis. Though a tall, large-boned woman, she only weighed a little over ninety pounds, and was obviously very much emaciated. He peeped down her larynx and to his surprise saw what he recognized to be a plate with artificial teeth firmly impacted in the larynx, where it had been for the last twenty-two months unknown to the patient. She remembered having been awoke in the middle of the night by a violent fit of vomiting, and when the teeth were inquired after it was assumed that they had been thrown away with the dejections. From that day forth, however, she suffered from difficulty in breathing, pain on swallowing, etc., associated with progressive emaciation. With some difficulty the plate was removed and exhibited to the admiring friends, and the patient rapidly recovered health and spirits.

Raori Resin.

The *Druggists' Circular*, December, 1890, says that a report from Noumea, by M. Formet, speaks favorably of the use of Raori resin —otherwise called Sydney gum or Caledonian balsam—as a suitable medium for the external application of antiseptics. It forms a coating over wounded surfaces. In cutaneous affections it is of great service; and also in the treatment of sprains and fractures when the limb must be kept rigid.

Disguise for Cod-Liver Oil.

A mixture of equal parts of cod-liver oil and lime-water is said to be nearly tasteless, but may be made more palatable by the addition of an aromatic syrup.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (Absolutely Harmless.)

Is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT, AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. E. R. Squibb, of Brooklyn, writes as follows in an article headed "On the Medical Uses of Hydrogen Peroxide (*Gaillard's Medical Journal*, March, 1889, p. 267), read before the Kings County Medical Association, February 5, 1889:

"Throughout the discussion upon diphtheria very little has been said of the use of the Peroxide of Hydrogen, or hydrogen dioxide; yet it is perhaps the most powerful of all disinfectants and antiseptics, acting both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. The few physicians who have used it in such diseases as diphtheria, scarlatina, small-pox, and upon all diseased surfaces, whether of skin or mucous membrane, have uniformly spoken well of it so far as this writer knows, and perhaps the reason why it is not more used is that it is so little known and its nature and action so little understood. . . . Now, if diphtheria be at first a local disease, and be auto-infectious; that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and a sufficiently repeated contact. . . . A child's nostrils, pharynx and mouth may be flooded every two or three hours, or oftener, from a proper spray apparatus with a two volume solution without force, and with very little discomfort; and any solution which finds its way into the larynx or stomach is beneficial rather than harmful, and thus the effect of corrosive sublimate is obtained without its risks or dangers. . . . ."

Further on Dr. Squibb mentions that CHARLES MARCHAND is one of the oldest and best makers of Peroxide of Hydrogen, and one who supplies it to all parts of the country.

CAUTION.—By specifying in your prescriptions "**Ch. Marchand's Peroxide of Hydrogen (Medicinal)**," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

A book containing full explanations concerning the therapeutical applications of both CH. MARCHAND'S PEROXIDE OF HYDROGEN (Medicinal) and GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{500}$ gr.), Codeia ($\frac{1}{50}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{60}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

88 Maiden Lane, **New York City.**

BURN BRAE

A PRIVATE HOSPITAL

--FOR--

MENTAL and NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

EXTENSIVE AND BEAUTIFUL GROUNDS, affording perfect privacy and pleasing variety. House and surroundings unusually attractive and cheerful. Heat, light and ventilation perfect.

A PLEASANT, SAFE AND HEALTHFUL HOME,

With constant professional supervision. Music, games, open-air amusements, boating, etc., are provided for patients.

THE OLDEST INSTITUTION OF THE KIND IN THE UNITED STATES.

Both sexes received. A limited number of opium habitues admitted. Pleasant companions for female patients.

LOCATED A FEW MILES WEST OF PHILADELPHIA,

At Primos Station, on the Philadelphia and Media Railroad, from Broad Street Station, Philadelphia, Pa.

Clinical Lecture.

VAGINITIS; ITS CAUSES, DIAGNOSIS AND TREATMENT.—DIAGNOSIS OF DEATH OF FETUS IN UTERO.

BY E. E. MONTGOMERY, M. D.,

PROFESSOR OF GYNECOLOGY IN THE MEDICO-CHIRURGICAL COLLEGE; OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL.

Gentlemen: Our first patient is a colored woman, thirty-five years old. She presents the following history. Her mother died of phthisis, and she herself was never very strong. She menstruated for the first time at sixteen; the flow was full, free, painless, and lasted on the average for three days. She has had four children, all living and well, has never had a miscarriage, and there is no history of venereal trouble. She menstruated the last time, the eighteenth of this month; after the cessation of the flow she felt sick and weak, and had considerable pain in the lower part of the abdomen, attended with a vaginal discharge, purulent in character. Her appetite is poor; her temperature on admission was between 102° and 103°, and has since ranged a little lower. Her abdomen is distended and tender, although there is no increase in tenderness upon pressure. Upon separating her limbs we see that the vulva is red in color, large, and with the posterior wall of the vagina protruding through it. The perineum, usually an inch and a half in length, is here only about half an inch long. The walls of the vagina are red and angry looking, showing at a glance that there is inflammation of the vaginal mucous membrane.

Inflammations of the vagina are divided into acute and chronic, specific and non-specific, catarrhal, diphtheritic, follicular and granular. Before entering upon the discussion of the symptoms and causes of the disease, it is well that we should devote a short time to the consideration of the anatomy of the vagina. The vagina, as you know, is a passage which leads from the vulva to the uterus. It is a musculo-membranous canal, and serves as the organ of coition and to convey the discharges from the uterus, and also affords passage for the fetus in parturition. Its wall consists of three layers—an outer layer of areolar tissue, a middle or muscular, and the internal, or mucous membrane. The mucous membrane is lined with pavement epithelium, resembling very closely that of the integument; this resemblance is still more marked where the vagina is exposed to the air or to friction with the clothing or limbs. The mucous membrane of the uterus has a columnar epithelium, this terminates at the external os. The mucous membrane of the vagina is thrown into folds called rugæ. Under inflammatory conditions, the swelling of the mucous membrane leads to the obliteration of these folds, and the outer layer of the epithelium is thrown off, so that it presents a smooth, glazed appearance, and imparts to the finger the sensation of passing over velvet or satin. In such inflammation we find: First, the mucous membrane becoming dry, hot and glistening; later there is increased secretion, the discharge presenting a whitened appearance from the presence of desquamated epithelium, or it is yellowish and greenish from the presence of pus and broken down blood. These latter conditions occur where the desquamation has gone on to the formation of points of ulceration.

Vaginitis may be caused as follows: First, from contact with specific poison; second, from the contact of various mechanical agents, such as may be used in the vagina for disinfecting or examining; third, from traumatism due to parturition, excessive or violent coition, or by the use of the

pessary; fourth, discharge from the uterus or sinuses, from abscesses opening into the vagina, such as pyosalpinx, or from the sac of an extra-uterine pregnancy.

In this patient the cervix is hard and firm, the body of the uterus is less resisting and is somewhat enlarged and flabby, it sags down from its increased weight, so that it is sometimes felt in a retroverted and at other times in an anteverted position. The tympanitis and tenderness show that there is threatened pelvic trouble, and extension of the trouble through the uterus into the Fallopian tubes, suggesting a possible peritonitis. This is still further demonstrated by the temperature and constitutional symptoms.

It is very difficult to distinguish between specific and non-specific vaginitis. Frequently the use of the microscope is essential to demonstrate the presence or absence of the specific micro-organisms in the discharges. It is not necessary that the discharge be specific in order to be infectious. Urethritis in the male may be easily developed by contact with the discharge from an endometritis. In this patient the condition is, without doubt, non-specific, from the rapidity with which the symptoms are subsiding under the simple method of cleanliness, which has been used. If it were specific, so marked an improvement would not occur so rapidly, or under such simple treatment. The purulent character of the exudation shows that the following process has occurred: the desquamation of the epithelium was followed by its decomposition, which, in its turn, produced inflammation, resulting in ulceration; the watery, milky discharge became yellowish and greenish in its appearance, and more viscid in its consistency. Bumm, in his investigation of the subject, has come to the conclusion that the vagina is rarely or primarily the seat of the specific infection; because the pavement epithelium, in its normal condition, proves a resisting wall to the entrance of the germ, while the columnar epithelium in the cervix affords a much more ready opportunity for its entrance, and is the common seat of its origin, while, from this point, it spreads to the vagina. Where the vagina has been the seat of repeated inflammation, a new inflammation sets up more quickly and extends with greater rapidity. On the other hand, the inflammation is more likely to spread to the uterus and tubes; and it is for this reason that we find tubal disease so frequently as a result of specific disorder. I would not wish to be understood, however, as affirming that all causes of tubal and ovarian trouble are due to specific origin; it is unjust to the character of many of our patients to assert this. Exposure to cold or dampness, the introduction of septic material through examination, either by the finger or by the use of instruments, may readily produce similar disorders in a patient who has been subjected to an inflammatory condition of the tubes, and who is very susceptible to recurring attacks upon the slightest exposure. Catarrhal inflammation in the tubes leads to increased discharge. So long as this can make its exit through the uterine end, the patient suffers but slight inconvenience; when the latter becomes contracted, as a result of the swelling of its mucous membrane, the discharge is likely to regurgitate into the peritoneal cavity, where it leads, at once, to inflammation which seals up the abdominal end of the tube. A sac is thus formed in which fluid is likely to accumulate, producing a condition known as hydrosalpinx. If septic germs, by any means, come in contact with it, we may have the fluid change, producing a pyosalpinx. Where the distended vessels rupture, and the tube becomes filled with blood, it is known as a hematosalpinx. As a sequel to inflammations which have extended from the vagina, we may have an irritable condition of the peritoneum at the tubal orifice, which is excited at each menstrual period, producing abdominal pain and tenderness similar to the irritation of the upper lip and margin of the nose from a catarrhal condition of that organ. Another possible sequel is extra-uterine pregnancy. Under the inflammatory process, we have the mucous membrane losing its ciliated epithelium, producing denuded points, or again the Fallopian tube is flexed, constricted, or so bound down as to have lost its peristaltic action, and the passage of the ovum to the uterus is delayed or hindered. On the other hand, the spermatozoa may find their way through the tube to the delayed ovum, leading to its fecundation and development in this situation. This is the theory for the development of tubal pregnancy. The advocates of this theory deny the possibility of abdominal pregnancy, except as secondary to rupture of the tube and escape of its contents into the abdomen. It does not, however, seem any more difficult to believe

that the ovum, having been fecundated in the abdominal cavity, may find opportunity, possibly from the previous irritation of the peritoneum, for its nutrition and development, than that the contents of the tube should take on new attachments after they have ruptured that organ. The possibility of abdominal pregnancy has been demonstrated in a case in which the uterus was removed supra-vaginally, an ovary having been left. Pregnancy occurred in this case and led to the death of the patient.

In the treatment of vaginitis, many cases are relieved by no other measure than strict attention to cleanliness, as in this patient, for whom the treatment has been simple washing out of the vagina with hot water, or hot water containing boric acid, which has here led to the subsidence of all the symptoms. Inflammation may be kept up by the want of removal of the exudations; frequent irrigating removes this material. In more severe inflammation of the mucous membrane, irrigation with astringent remedies is very beneficial. Avoid syringes which force the water with violence into the vagina. Use in preference a fountain syringe, placed about three feet above the patient, and allow it to be used while she is in a sitting or semi-sitting position, to permit a free return of the fluid, whereby ballooning of the vagina is prevented. Inject several times, two quarts of water at one sitting. Keep the nozzle of the syringe below the uterus, and move it about, this precludes the entrance of water into the uterus, which might give rise to violent attacks of uterine colic and increase the danger of septic material being washed into it. One of the most effective preparations for injection is a sublimate solution in the strength of 1, 2, 3 or 4 to 1,000; which may be followed by some astringent, such as sulphate of zinc—40 to 60 grains to the quart. Acetate of lead, gallic acid, tannic acid or extract of hydrastis (which is another form of tannic acid), may be used. If the removal or sterilizing of the discharge is incomplete, it is important to supplement this treatment by placing the patient in the Sims's position and go over the mucous membrane with a mop, containing some such agent as nitrate of silver, in a two per cent. solution. By the use of a Sims's speculum it is possible to reach the summit of the posterior and anterior fornices of the vagina, and the posterior surface may be reached as the instrument is withdrawn. In very many cases the application of the remedy with a spray is a very effective method, as the evenly-divided material is driven into the cracks and crevices not touched by the mop.

Where extensive ulceration exists, still further treatment is essential. The vagina must be tamponed to keep the surfaces apart. Gauze is the best agent for this, and that made with iodoform is the least irritating. This can be packed in lightly, or the whole vagina may be plugged. The gauze can be placed in dry, or wet with some antiseptic solution.

In follicular vaginitis this treatment does not suffice. In such cases we find the true layer of epithelium is gone, and in its place is a growth of papillæ. It is necessary to destroy these papillæ. Generally the best agent for this purpose is the thermo-cautery.

There is a form of granular vaginitis which is apt to occur in women of intemperate habits, especially if they have passed the climacteric. It is in reality a senile vaginitis, and is likely to proceed as long as indiscretions in diet and drinking are kept up.

Vaginitis is likely to appear in plethoric subjects with a gouty diathesis. In the latter case all blood conditions must be improved. In all cases, remember that there is danger of extension if the case is not properly treated. In displacement of the uterus its cavity may be dilated. Its contents are not freely drained, and may be discharged at intervals, giving rise to the impression on the patient that she has had an abscess discharge. This material is exceedingly irritating, and invariably gives rise to inflammation of the vagina.

From what I have said of the cause and treatment of vaginitis, you will readily perceive the importance, in every case, of examining carefully as to the conditions which may have originated it, and of directing your treatment to correction of the conditions by which it has been caused. This demonstrates that you cannot divorce the special from the general practitioner without disadvantage to the doctor and patient.

Death of Fetus in Utero.

Our next patient is another colored woman, twenty-three years old. She has always had good health, and seven years ago gave birth to a child at seven months. Since that time she has been regular. She saw her menses last in March of this year. She has suffered with nausea, which was

brought under control; and movements of a fetus were felt in August. But at each monthly period she has had a slight appearance of the menses. She has reached the seventh month of pregnancy, but the question we have to decide for her, is: Is her child living? She has felt no fetal movements for two weeks. The fetal movements are usually felt first at four and one-half months, so women are accustomed to reckon from this period four and a half months to the time of the expected confinement. This is, however, unreliable as a date, as movements have been felt, occasionally, as early as the fourteenth week; and Underhill has mentioned a case in which the patient felt the movements at the eleventh week. The first sign is a sliding, gliding, quivering movement, which usually gives rise to nausea, faintness or sickness. It has occurred, however, that the woman would go through the entire period without a single movement of the fetus. This is due to the fact that the fetus is held tightly in the membranes, which contain but little fluid, so that its opportunity for movement is slight. The absence of fetal signs is not, then, a positive indication of disease or death of the fetus. Ordinarily at the seventh month the fetal movements become stronger and more frequent. Sudden death of the fetus is often preceded by violent convulsive movements, followed by subsequent total cessation. This may be due to some disease in the fetus or in the placenta, or to twisting or knotting of the cord. When the fetus dies the abdominal walls become flaccid, and the fetus can be pushed from side to side without exciting any resentment. It lies perfectly passive, when before it would resist movement with a kick or blow. Another indication of death would be the absence of the fetal heart sounds. These sounds are not always heard. When the fetus is turned with its back to that of the mother, and does not approximate the anterior part of the abdomen, the fetal sounds may be absent, and the fetus still in a healthy condition. If the sounds have been repeatedly heard and then suddenly disappear, this, with the other suspicious symptoms, would justify us in suspecting the death of the fetus. This is especially true when external examination demonstrates the fact that the fetus is in such a position that its heart sounds should be readily heard. Fetal death is still further confirmed when the breasts of the mother become soft and relaxed. This indicates that Nature recognizes the fact that there will be no demand made on them for nourishment. As the dead fetus undergoes changes, auscultation may give sounds like crackling and bubbling, which arise from the generation of gas and its passage through fluids. The patient will also complain of constitutional impairment and lassitude. All these signs are present in the patient before us; so that I have no hesitancy in saying to her that the fetus is positively dead. The cause of her trouble is probably a fatty degeneration in the placenta, by which its vessels are interfered with, and nutrition is arrested. This trouble is due to a specific cause; the woman is syphilitic. [This patient was delivered a few days later of a macerated fetus.]

COMMUNICATIONS.

HYGIENE OF INFANCY.[1]

BY GEORGE N. HIGHLEY, M. D.,
CONSHOHOCKEN, PA.

There is perhaps no single topic about which so much has been written and spoken as the care and management of infancy; and I should deem my subject too trite to bring before this Society, were it not for its great importance, and for the fact that each of us has to deal daily with the problems arising therefrom. Further, it is a duty which we owe to Science and, greater still, to Humanity, to constantly observe and study those facts which will aid us to pilot the little ones safely over that dangerous period, during which so many fall victims to disease and death.

With our advancing civilization Society is constantly making the infant's environment more unhealthy; daily making more difficult its struggle for existence.

Science is ever giving us new facts about the cause and nature of disease; but little progress is made in their prevention or their treatment. What does it avail that we are able to detect the cause of disease in living germs, so long as we allow to remain around us fertile fields for their propagation, and have no practical means of protecting the system from their deadly influence?

In dealing with the problem, how best to conserve the health and lives of the little

[1] Read before the Montgomery County Medical Society.

ones—we naturally turn our attention to those elements and conditions which experience has shown us to be deleterious to them. These are: excessive heat, impure air, water and food, improper kind of food and food improperly administered, errors in clothing, bathing, etc. I have purposely placed excessive heat first on the list, because its influence in the causation of the diseases of the digestive system of infants is greater than all the others combined, taking them as we usually find them. I do not underrate the evil influence of polluted air and water and food, and of improper and irregular feeding; these are bad enough, to be sure; but their harmful effects are decidedly mitigated by a cool atmosphere, so that in winter death from a diarrhœal disease is quite exceptional. On the other hand, the excessive heat of summer carries off many victims that have been nursed at the breast and have had their hygienic conditions as favorable as possible.

Cases like the following are of frequent occurrence. A child in the sultry summer weather becomes peevish and restless; its head is hot, its mouth and lips dry. The mother feels its gums and discovers that it is teething (it is well to remember that children are always "teething" during the first two years of life). Should the infant continue ill, a physician is summoned; if no diarrhœa or vomiting has occurred, he is apt to agree with the mother, prescribe a bromide or an opiate, or perhaps scarify its gums and pass on. If there has been stomach and intestinal derangement, he will likely inquire carefully into the character of its food, the methods of feeding, etc., correcting any errors in these. He prescribes some medicines, and expects that he will find it much better on the following day. Too often he does not; too often he finds it with a pinched, anxious expression, sunken eyes, cold extremities and with frequent vomiting and purging—in a word, that it has cholera infantum and that its chances of life are very slim. It is possible, perhaps probable, that a large number of the little patients affected in this manner would make a speedy recovery if early treated with cold affusion; and if their mothers and nurses but knew the important part that heat plays in causing these complaints and as diligently guarded their babes against the ravages of summer's heat as they do against the chilling influence of winter's cold, cholera infantum would have a great many less victims.

If the home is a one or two-story dwelling in a crowded street, unprotected by trees, or otherwise, from the glare of the sun, it is often a difficult matter to shelter the infant from the external heat. But even in the most unfavorable conditions, much can be done. The child should be dressed lightly—a light, thin woolen shirt (made of the finest lamb's wool if possible), neatly fitting and long enough to reach the hips, with a thin dress, is all the clothing required for the body. If the weather becomes cooler, more clothing can easily be added.

The child should also have frequent baths—not with wash-rag and soap and a basin of water—but immersed in a tub of water at a temperature of 85°, and less as it becomes accustomed to it. It should remain in the water only a few minutes, of course.

The infant should also be taken out regularly in the early morning and in the cool of the evening, to some locality where it can have a good supply of pure air. In the midday let it take its nap in the coolest and airiest room the house affords; if this is necessarily a hot one, the morning and evening rides and the cool baths will do much to enable its system to endure it.

The thought of pure air and water brings up questions in general hygiene that I need not enter into here; it will be sufficient to repeat a well-known truth, namely, if the streets, alley-ways and back-yards could be kept free from all decomposing organic matter, a most important factor in the etiology of disease would be removed.

The question of infant feeding continues to be one of supreme importance. High temperature and bad food are the two prime factors in causing the diseases that annually carry off so many little victims, and in a measure they depend each upon the other for their pernicious effect.

It is conceded by all that the natural diet of the infant—the mother's milk—is the best that can be given it. Of the large number of deaths from cholera infantum in our large cities, only three per cent. occur among infants fed at the breast, while over 90 per cent. are bottle-fed babies. Naturally it would seem that every effort ought to be made to help the mother nurse the child. I venture the assertion that the person who can invent or discover a remedy that will promptly cure an eroded nipple, will have invented or discovered a means of saving thousands of human lives.

The second best food for the child is un-

doubtedly cow's milk, modified so that it shall closely correspond in chemical composition to mother's milk. There have been numerous attempts at accomplishing this. Many mixtures have been devised, and the market has been flooded with patent foods, all claiming to be perfect substitutes for the milk of the mother. A careful comparison, however, will show that, in nearly all of them, there is a wide departure from the natural food. The following mixture, recommended by Dr. T. M. Rotch, in the *Cyclopedia of the Diseases of Children*, approaches as near to it as any that I have seen, and thus far it has answered well in the cases in which I have tried it. It is really a modification of what is known as the "Meigs Mixture," and is made as follows. For an ordinary 8-oz. nursing bottle: Milk, 1 oz.; lime water, ½ oz.; cream, 1½ oz.; milk sugar, ½ oz. (3⅓ drams); water, 4½ oz. The objections to this are, that at first its preparation seems a trifle troublesome, and, second, that it is somewhat expensive—a matter of some consideration to the poorer classes. It is, however, quite as easily prepared as many manufactured infants' foods, and does not cost any more—at any rate, it is much less expensive than a funeral.

There are other matters, quite as important as the kind of food, which should have careful attention. These are: the quality of the food and the quantity, and the method of its administration.

Pure, unaltered milk, no matter how it may be mixed, is absolutely indispensable to the well-being of the infant. If it can be procured shortly after it is milked from the cow, and placed on ice, that is all that is necessary. If it cannot be obtained until it has been carried around in cans for several hours, then it should be boiled and bottled—the mouth of the bottle being stoppered with a pledget of cotton—after which it is placed on ice, or in pans of cold water if ice cannot be obtained.

Having procured and prepared a good food, the next question is that of its administration. Errors in this are frequent and serious. Early the infant should be taught to want its food at regular intervals—never less than three hours. If this be carried out, errors in quantity will be little likely to occur. The child's desires will be a good index of how much it ought to have. The reprehensible practice of giving babies bottles with long tubes, and letting them alternately sleep and suck for hours, is so obviously bad that mere mention of it is sufficient.

Of the various methods of peptonizing milk, little need be said. For a baby whose digestion has been temporarily overtaxed, they may be used with much benefit for a short period. Used regularly, they do harm by seriously interfering with the normal digestion—diminishing the secretions of the natural digestive ferments.

The following rules of guidance seem to me to be as near correct as the present state of our knowledge will warrant.

Use every reasonable effort to have the mother nurse her child. If this is impracticable, endeavor to obtain a supply of pure cow's milk twice daily if possible. Use the best means possible to protect the milk from fermentative changes (or from bacteria if you choose). Modify it in the way that I have described, if possible; otherwise give it pure or simply diluted with water and a little lime water. Give it at regular intervals, and never at shorter intervals than three hours. A single feeding should not occupy over half an hour; nor, on the other hand, should the milk be taken too rapidly. After using, the feeding bottle should be thoroughly scalded and cleansed. Clothe the infant lightly in hot weather. Bathe it frequently, using soap sparingly. Keep it in the outside air as much as possible, especially in the early morning and in the cool of the evening. Above all, remember that heat is a most important factor in the causation of disease.

RESORCIN.

BY ALFRED EICHLER, M. D.,

SAN FRANCISCO, CAL.

Resorcin is an article deserving of more attention than it has hitherto received. It occurs in rhomboid prismatic crystals, white and shining in its pure state, with a sweetish taste and a somewhat pungent smell. If exposed to light or kept in a moist place it will soon acquire a reddish tinge, but it does not lose its activity. It is soluble in water and alcohol, also in ether. Solutions assume on standing a darker, whiskey-like color, without any impairment of their activity. In very concentrated solutions it acts as a mild caustic, if applied to mucous membranes; it does not irritate sound skin, however. When sufficiently diluted it seems to have a sooth-

ing effect on inflamed surfaces and also on the mucous membranes. Internally it may be administered in doses ranging from two to fifteen grains.

Resorcin belongs to the phenol group; its medicinal qualities therefore resemble somewhat those of carbolic acid. It arrests fermentation and decomposition, and hence possesses antiseptic properties like its congeners. It is to be preferred to carbolic acid in all instances when the latter proves too irritating. Consequently it is especially useful in all affections of the mucous membranes; it is then used in aqueous solution, largely diluted. A three to five per cent. solution is mostly preferred. In catarrh of the posterior nares and of the pharynx it is found to be an excellent application; it is also useful in all affections of the upper air-passages. Here it is preferable to almost any other antiseptic; an aqueous solution may be used ad libitum, and can do no harm if swallowed in ordinary quantity. This alone would be a good reason to prefer it to bichloride of mercury or carbolic acid; but it also improves the local conditions quickly and gives great relief to the patient. For this purpose it can be combined with other substances. A good formula is presented by the following:

℞	Resorcin	2 drachms
	Salicylate of soda	1 drachm
	Biborate of soda	1 "
	Glycerine	2 fl. ounces
	Water to	8 "

Mix and dissolve. S. Use freely three times daily.

This solution will soften and bring away all hardened secretion, relieve the congestion and lessen the usual discharge. For thus cleansing the naso-pharynx a posterior nares syringe should be used instead of a nasal douche, which in unskilled hands is very likely to create mischief, that is, inflammation of the middle ear. This can be caused by the patient performing the motion of swallowing while the liquid passes the orifice of the Eustachian tubes, connecting the naso-pharynx with the middle ear. During this act the tubes open and a small quantity of liquid may pass up into the ear and give rise to a severe inflammation. A posterior nares syringe will do the cleansing equally well, if not better, and does not endanger the patient.

In many other affections of the air-passages does resorcin give great relief. Whooping-cough, asthma, bronchitis and laryngeal ulcers are benefited by it. It is especially valuable in chronic ailments of this kind; it is of less use, however, in the acute affections, like croup and diphtheria. It should be applied in diseases of the throat with an atomizer spray or inhaling apparatus. A five to ten per cent. solution will serve all purposes.

Resorcin sometimes acts charmingly in other diseases of the mucous surfaces; it is an excellent injection in all stages of gonorrhœa, although it here also produces more benefit during the latter stages; in inflammation of the neck of the bladder it may also be employed. From two to five per cent. solutions will be the proper strength to use.

During the last few years some of the leading dermatologists have praised resorcin as an efficient remedy in various diseases of the skin, especially those of a fungous origin. It may be conceded that it does exert considerable influence in this way, but it must also be acknowledged that resorcin is much inferior to chrysorobin in this respect. In very old skin affections, like eczemas of long standing, where the skin needs stimulation, it is quite useful and recommends itself by not producing any stains or other disagreeable consequences, besides being completely harmless.

Resorcin may be elegantly dispensed in ointments having lanolin as a base and containing from 10 to 20 per cent. of the active ingredients. It can also be applied dissolved in ether and collodion, and will then form an excellent antiseptic protective.

The internal use of resorcin is chiefly limited to producing its antifermentative action. In gastric and intestinal catarrh, dilatation and ulcer of the stomach and in all those diseases where gases are produced in the alimentary canal, its use is indicated. Impure resorcin is said to occasion vomiting, but, according to Andeer, pure resorcin is one of the very best and most certain remedies against vomiting, and he says that it will prove efficient in all possible forms of vomiting, as in those caused by pregnancy, kidney and liver diseases, also by sea-sickness and after excessive eating and drinking of alcoholic liquors. The doses as applied by him range from five to forty grains. It is most conveniently administered in capsules.

Resorcin has also been recommended, like many other antiseptic drugs, in the strictly septic states, like puerperal fever and

erysipelas. It is of little or no use for this purpose.

An advantage of this drug consists in the fact that aqueous solutions of resorcin possess no smell whatever, and also, that they may be combined with alkalies in any proportion without losing their antiseptic value.

FATAL HEMOPTYSIS FOLLOWING TYPHOID FEVER.

BY STANLEY M. WARD, M. D.,

SCRANTON, PA.

I have purposely abstained from entitling this communication hemorrhage, a sequel of typhoid fever (using the term sequel as it is commonly used in medicine, viz., as following or dependent on the antecedent disease) for two reasons: first, because of my utter failure to find anything like it in my search through the standard medical works and periodical literature of the day, and secondly, because the history of the case reveals peculiarities which some may think militate against this view. I have therefore thought best to term the hemoptysis a sequel only as regards *time*, though I am of the opinion that it was a sequel both as to *time* and *cause*.

History, personal and family of E. B., male, 21 years old. Habits excellent; works as a skilled laborer in a stove foundry, the air of which is said to contain minute particles of iron and steel; is catcher for a strong amateur base-ball club and is also an athlete. During the past three years at long intervals—just how many times is unknown—he has, after severe exertion, spat up a little blood. He never experienced any ill effects therefrom, and was always well and hearty. He works every day, and has lost neither appetite nor flesh. Mother—the only member of the family not living—died ten years ago of acute pneumonia. Has three brothers and two sisters, who, with the father, are perfectly well. On August 29 he had a general feeling of malaise, chilliness, headache, etc. Bowels a little inclined to be loose. Worked but half the day. On the 30th and 31st, these symptoms continued, though domestic remedies and fair sized doses of quinine were taken. He did not feel sick enough to remain in bed, but did not work. His appetite was nil. On September 1, he took a short trip, and was gone all day. On returning in the evening he remarked that he "never felt so tired before in his life." He arose the next morning, however, feeling much as he had before. I saw him at 2 P. M. of this day, having gained the information herein given. No record was made of the last blood spitting, but he thought it occurred some time in the spring. A careful examination of the chest revealed no lesions of heart or lungs—which somewhat surprised me. His pulse was 100, his temperature 102½°; he had had two passages from the bowels that day, he complained somewhat of pain on pressure over the abdomen. He also had some headache. The diagnosis was reserved. On September 3 his morning temperature was 101½°, and his bowels had not moved again. He had no cough. There were one or two poorly defined spots on his abdomen, and slight iliac gurgling. His mind was clear and he insisted that there was nothing the matter, except that he was tired.

I now diagnosticated walking typhoid fever, and put the patient to bed, ordering a liquid diet and a few drops of acid to be taken several times daily, also sponging with lukewarm water twice daily.

So, for ten days more his symptoms remained. Sometimes his temperature would reach 103°, and sink to 101° in the morning. Sometimes the bowels moved naturally, and sometimes he required a little glycerine to secure a stool. A few more spots appeared on the abdomen. Indeed, hardly a symptom was lacking of a typically mild case of typhoid fever.

On September 13, his temperature was 99°, and on the following day reached to normal, remaining there also at night. He now became very anxious to eat, and it was with some difficulty that his appetite was appeased. On September 16 he sat up and was partially dressed. On the next day he walked a little way out of doors, sending a message to me that his people were starving him. On September 20 he did not leave his room, complained of headache and coughed some; and these symptoms continuing, I was sent for in the afternoon. I found him in bed, looking anxious and tired. He felt certain that a relapse was to occur, and was much discouraged. His pulse was 120, his respiration 25, his temperature 103½°. A short, hacking cough was very presistent, and his lungs now showed signs of bronchial irritation, râles of every kind being plentiful. From all the rational and physical signs, I looked for an attack of

catarrhal pneumonia, and so expressed myself. He was ordered a lukewarm bath, and given eight grains of antifebrin, followed by a full dose of aromatic spirits of ammonia. At 9 P. M. his brother informed me that his temperature was 101½° and his breathing more easy, and also that he had raised some blood. He did not know whether the blood was mixed or unmixed with the sputa, and evidently thought the patient a great deal better.

I saw him at 8 A. M. the following morning. He was weak, looked ensanguinated, his pulse was feeble, 130, his temperature 103°, his breathing rapid. He was then expectorating nearly pure, red blood, and from the vessel in the room I judged he had lost nearly a pint. Recognizing the extreme gravity of the case, I requested Dr. L. as counsel. He joined me a short time thereafter, and recommended giving gallic acid in addition to the ergotine I had given hypodermically, with other approved measures. We went over the case from its incipiency, and though differing as to the exact cause of the hemoptysis—whether due to pre-existent lung trouble or a direct sequel of the fever—neither of us hesitated to diagnosticate pulmonary hemorrhage or to give an unfavorable diagnosis. The lungs were not hepatized, but the air produced a slushing sound as it passed through the bronchi and entered the ultimate lobules, as though they were partially filled with liquid. The patient gradually failed, and died of exhaustion at noon on September 22.

The question naturally arises: Was the hemoptysis dependent on the attack of fever through which he had passed? Unless this be answered in the affirmative, one is almost forced to conclude that the patient had phthisis prior to August, and was suffering from its ravages even while appearing hearty and well, exhibiting no symptoms, except a slight loss of blood after hard exertion, rational or physical. This opinion, I am forced to say, was my consultant's; but it leaves unexplained the patient's apparent health and the week of convalescence.

Readers of Da Costa's *Medical Diagnosis* will recall the cases there alluded to, of hemoptysis occurring without perceptible lung lesion. I do not think, in this case, the attacks of bleeding prior to the fever had much, if indeed any, connection with the fatal one. I believe that had the man lived, phthisis from hemorrhage would have existed—cases of phthisis being recorded as following typhoid fever—but that the first symptom, hemoptysis, was too severe for his enfeebled system to overcome, and so death resulted.

Although I believe hemorrhage from the lungs in typhoid fever is by no means unknown, it seems very strange that I failed to find, after a search quite thorough in its character, any recorded case of hemoptysis following typhoid fever. I trust the extreme rarity of the case will be a sufficient excuse for reporting it at this length.

REMARKS ON INFLUENZA.

BY J. CHESTON MORRIS, M. D.,
PHILADELPHIA.

I wish to place a fact on record at this meeting of the College, and a hypothesis as to the nature of the epidemic influenza which we have all been treating during the past eight months.

The fact is this: In December last I was called to see Mrs. W., living on Thirteenth street, below Lombard, and found her suffering from a severe attack of the "grippe." Her first remark to me was, "Doctor, I am attacked by the same cold you cured me of last August." On turning over my notebook I found that I had in August recorded her case as influenza.

Now, then, for my hypothesis as to the nature of this singular malady. We have had it recurring more or less irregularly, with greater or less severity since 1842. Each epidemic has been marked by symptoms of its own—in one year the force of the disease would seem to expend itself on the throat; in another, on the mucous membranes of the eyes and nose; in another, on the bronchial surface. In all, as in the epidemic of this year in a more specially marked manner, there has been one feature in common of this Protean disease—that of debility, prostration of strength and vital energy. The first uncomplicated fatal case in this city, I believe (that of Mrs. C., on Thirty-eighth street, above Market), was one of simple loss of power in heart and lungs. From what I have since seen, I believe that the death of Professor S. (Lombard street, below Fifteenth), whom I saw in consultation at the close of what his attending physician called a low nervous fever, preceded by repeated alarming attacks of heart-failure and pulmonary congestion,

was due to the same cause. This view, that there is a loss of power of the heart and lungs to perform their work is, I believe, shared by the great majority of observers. But this epidemic has been characterized by three other sets of symptoms: First. Violent neuralgic pains in various parts of the body. Second. Intense mental and nervous depression, out of all proportion to any physical signs to be detected; people "never felt so ill in their lives;" strong and active men became nervous and apprehensive in a manner and to a degree to alarm all who knew them. Third. Many suffered (and of this form of the disease I have seen a number of cases lately) from a loaded condition of the sigmoid flexure and rectum, with constant straining efforts at stool, ineffectual except in the discharge of a little glairy mucus, and with sharp, cutting, colicky pains due to gaseous distention of the colon.

These symptoms—the failure in heart and lungs, the abdominal sufferings and the neuralgic pains—all point to a neurotic cause, such as the paresis or partial paralysis of the pneumogastric nerve. And this I believe to be the true nature of our epidemic. I have fought it accordingly, since I recognized it as such, with stimulating doses of whiskey, opium and strychnine, watching for recurrences and relapses, and treating them as they took place.

If we were to look for a cause of this paresis, affecting so many persons at once, scattered over so large a portion of the northern hemisphere, traveling more rapidly than by human modes of transportation, or following other than ordinary lines of communication, where should we be so likely to find it as in a state of the atmosphere which rendered the process of breathing more difficult and exhausting than it ordinarily is? Some slight change of barometric pressure, or of humidity, would give ample occasion for fatigue of the pneumogastric and other nerves controlling respiration and circulation, the effect would be felt in each system in its weakest spot, and we would have thus an explanation of the very various symptoms and phenomena presented.

The above remarks were made by me at the meeting of the College of Physicians last June, and were subsequently embodied in a paper read before the Academy of Medicine at its recent session in this city. Practical experience of the benefits resulting from the administration of tincture of nux vomica, in doses of from ten to fifteen drops every three or four hours, in cases of depression of pulmonary and circulatory function, leads me to commend it to the consideration of the profession.

1514 Spruce Street.

PELVIC ABSCESS IN A MAN: SPONTANEOUS CURE OF HERNIA.[1]

BY DAVID S. BOOTH, JR., M. D.,

BELLEVILLE, ILL.

The following case of pelvic abscess came under my observation while surgeon in charge of the International and Great Northern Railway Hospital. While authority justifies Gross in saying, "the diagnosis of deep-seated abdominal abscesses is sometimes extremely obscure," I think this was unusually so, owing to the urinary symptoms occasioned by pressure upon the bladder and urethra; at any rate, not one of the half dozen physicians who had been connected with the case, was able to arrive at its true nature until a free incision had been made, and the cavity had been explored with a probe. The urinary symptoms were misleading; and I find upon referring to the case-record which is in my possession, that my diagnosis, made upon the patient's admission (as required by the hospital rules) was, "abscess of bladder (?)," which was revised by substituting "abscess of cavum Retzii," or the prævesical space.

About March 25, 1888, A. G. M., a locomotive fireman, 28 years old, applied at the hospital for what was diagnosticated by the assistant house surgeon who attended him as cystitis; but the patient, receiving no relief, fell into other hands; and it was not until April 24—a month later—that I admitted him to the hospital, and obtained the following history.

About five or six weeks before, he had noticed a hard lump in the hypogastric region and pain about the neck of the bladder during micturition. He noticed no alteration in the color or character of the urine, and had no fever. His bowels were in good condition—in short, he considered himself in good health, and continued at work for some ten days after he first noticed the swelling. He stated that the swelling had increased in extent of surface involved;

[1] Read before the Southern Illinois Medical Association, November 21, 1890.

that he had had fever lately; that his urine was high colored and his micturition more frequent, causing him to pass urine several times during the night; and that his stream had diminished in size. He had noticed no sediment in the urine. He had had gonorrhœa two years before, which gave him no unusual trouble. His bowels were costive but no pain accompanied the act of defecation. His tongue was coated centrally with white fur. He did not remember receiving any injury.

Examination of the hypogastric region revealed a hard, circular intumescence, some six inches in diameter, but not very prominent; tender upon light pressure. The man's pulse was 96; his temperature 101$\frac{2}{5}$° Fahr.

Examination of the urine resulted as follows: color, somewhat darker than normal; flocculent; faintly alkaline in reaction; sp. gr. 1.020; trace of albumin. The microscope revealed pus corpuscles and squamous epithelium.

In attempting to pass a catheter, with a view to ascertaining the condition of the urethra, as well as to learn whether or not there was retention of urine, I found the membranous portion of the urethra diminished in caliber to such an extent as to permit the passage of a filiform bougie only. The patient was given the fluid extract of pichi and quinine, and gradual dilatation was performed, until I could pass a No. 14 English bougie. As soon as urethra permitted, the bladder was washed out every day or so with Gerster's solution of salicylic and boric acids.

On May 7, twelve days after admission, the tumor was not so painful and it pitted on pressure. The urine was more natural in appearance, and the micturition less frequent. As suppuration was evident, moist heat was ordered to be applied.

On May 9, palpation gave an indistinct sense of deep fluctuation, and the tumor was aspirated, the needle being inserted about one and one-half inches to the left of linea alba and about three inches above the pubes. About seven ounces of a dark fluid, having the consistency of cream and a stercoraceous odor, was obtained.

On May 12 the aspirating needle was again inserted, but the fluid being too thick to flow through the needle, an incision about one and one-half inches long was made, to the left of the linea alba, when about ten ounces of fluid, having the same offensive odor as before, was discharged.

The patient improved rapidly, the urinary symptoms disappearing at once, and he was able to lie on either side—the dorsal decubitus alone was possible previously. He was discharged at his own request June 23, nearly two months after admission. When I saw him last, some eight months after his discharge from the hospital, he informed me that his health had been excellent and that he had been at work for some months. He further informed me that he had been *cured of a right oblique inguinal hernia.*

As my intention was to report the case without prolixity, I have failed to call special attention to the absence of those symptoms of abscesses in general which have the most diagnostic import: namely, rigors, perspiration and pain, from the latter of which he was quite free, except upon movement and during micturition. Furthermore, in arriving at the diagnosis, we were mindful of the fact that other abscesses occur in and about this location which were to be excluded, and especially were we conscious of the probability of perityphlitis with the cæcum and appendix vermiformis in the hypogastric region, an occasional anomalous position. Without attempting to confirm the diagnosis by exclusion, I will conclude with the following hypothesis in regard to the spontaneous cure of his inguinal hernia.

As the patient wore a truss and his occupation—locomotive fireman—required him to be a great deal of the time in the stooping posture, and to make strong exertions in this posture, inflammation of the fascia transversalis was set up; and, as this fascia forms the internal abdominal ring as well as the inner wall of the inguinal canal, obliteration of the canal had resulted, and a cure of his hernia.

PERISCOPE.

Resection of Prostate for Enlargement.

In the *Medical Press,* December 3, 1890, Mr. R. F. Tobin, Surgeon to St. Vincent's Hospital, says: Clinical and pathological experience have I think settled the following points:—(1) That there may be considerable enlargement of the prostate without any stoppage of urine. (2) That when there is permanent retention it is due in nearly all cases to a prominence which when pressed upon by the urine closes the internal orifice of the urethea. It follows that to do away

with the obstruction it is necessary to remove as much of the gland as is in the way and no more. This can, I think, best be done in the manner adopted by me for the relief of the patient whose case I here relate.

J. K., æt. 60, was admitted May 31, 1890, into the St. Vincent's Hospital, Dublin, for retention of urine due to an enlarged prostate. For eleven years he had suffered more or less from this ailment, and had been treated for it both by me and my colleagues. On the last of these occasions, about four years ago, I made a digital examination of his bladder through a perineal incision, but not being able to ascertain thereby anything more definite than what was already known, that there was an enlargement of the prostate, I used the incision merely to drain the bladder and cure thereby a cystitis that was then adding greatly to his sufferings. The history of the years that intervened between that operation and his admission on the present occasion is the ordinary one of a poor man who cannot make water without the use of an instrument. A rough catheter and a raw urethra sketch it sufficiently. When admitted he was emaciated and in a bad state of health, there was a tendency to the formation of bed sores on every prominence, the urine was fetid, he had hourly calls to micturate and could do so only through an instrument, the passage or retention of which gave intense pain.

The following operation was performed on May 9. A supra-pubic cystotomy having been done in the usual way, a digital exploration showed the middle and left lobes of the prostate to be much enlarged. The enlargement was a ridge, about an inch in height and an inch at its base, surrounding and overlapping two-thirds of the urethral orifice. Although the whole appeared to be one mass it was only so by contact, for the finger could be passed between the lobes. The instrument used to shave off this protuberance was an écraseur extemporized in this way. A wire doubled and bent to a suitable curve was passed through the urethra into the bladder. A silver catheter was then slipped up along it, but its point in place of being passed into the bladder was made to impinge against the urethral obstruction. Next the double wire lying in the bladder was opened out into a loop and slipped over the enlarged middle lobe and was kept embedded round its base by means of two fingers passed through the abdominal incision; while this wire was being made to cut its way through the part it encircled, the inserted fingers helped by the point of the catheter, which was depressed to the spot it was desired to reach, regulated its direction. I was surprised how little resistance there was to its progress. As the lateral lobe was not of a shape to be encircled by the wire it was necessary to divide it into two by nicking it deeply with a scissors. Each half was then dealt with as had been the middle lobe. The surface left was found to be smooth and to slope into the urethra. There was little or no bleeding. Copious irrigation with warm boric lotion and a partial bringing together of the edges of the wound (the low vitality of the patient gave no prospect of immediate union) completed the operation.

The chief points noted during the subsequent progress of the case were sloughing of the cellular tissue in the immediate neighborhood of the abdominal incision; extension of the bed sores noted as existing when admitted; uremic delirium for ten days with a large amount of albumin in urine (about one-sixth). These complications notwithstanding, the patient made a good recovery. Most of his urine passed away through an india-ruber tube to a vessel alongside his bed. What urine overflowed was absorbed by large peat-moss cushions placed under the patient. The house diaphoretic mixture containing liq. ammon. acet., pot. nit., and spirit æther nit., seemed to favorably influence the uremic condition.

On the twenty-second day after the operation the tube—a smaller one than originally inserted—was withdrawn from the abdominal wound now nearly healed, and a catheter was passed by the urethra and left in.

On June 16, the patient was allowed up, and a few days later, about seven weeks after the operation, on being asked how he was, he answered, "I can make water as when I was a boy of fifteen." This sentence must be taken rather as expressing his wonder at the change that had been effected in him than as an accurate statement of his condition. As a matter of fact, he could contain about half a pint of water, and passed it without pain or difficulty in the usual way. A week later he was discharged.

The parts removed are three masses, each about the size of a small walnut. Mr. Patteson, who has microscopically examined these, has found in them nothing but hypertrophied prostatic tissue.

The method of resecting the prostatic gland here set forth has I think the following advantages:—

1. As much of the gland as interferes with the escape of the urine is removed and no more.

2. The portion that blocks the urethra is removed in a satisfactory manner, for the wire cuts up to the point where the instrument has been stopped by the obstruction.

3. A smooth surface sloping into the urethra is left instead of the more or less rough one that must result from taking away the gland piecemeal with a forceps.

4. There is very little hemorrhage.

I do not know that in all cases a wire would cut its way through an enlargement as easily as it did in the instance now related, but this difficulty could be overcome by preparing a bed for it with the point of a knife or scissors. Only in the coverings of the gland need any resistance be expected, its friable substance is easy of division with any instrument.

Nov., 1890.—It is now six months since the performance of the operation. The outlet from the bladder continues quite free, and the power of retention improves with the lapse of time. The general condition of the patient is also much improved.

Products of Pathogenic Bacteria.

During the past two years great progress has been made in the study of the action of pathogenic bacteria. This work has chiefly been carried on by Koch and Pasteur on the Continent, and by Drs. Sidney Martin and Hankin in England. In the *Revue de Médecine*, 1890, No. 7, Dr. Charles Bouchard publishes an article on the properties of the substances secreted by pathogenic micro-organisms. It contains the chief part of his address before the Tenth International Congress on the "Mechanism of Infection and Immunity." After an exhaustive summary of all that is known concerning the action of products of metathesis with which we are acquainted, Bouchard relates a series of thirty-one experiments which he made, partly in order to investigate the power which blood-serum possesses of destroying bacteria, and partly to ascertain how far their products confer an immunity against similar or other bacteria. Many experiments demonstrated the influence of the same products on phagocytosis. The space here is too limited to enter into the details of this interesting paper, but the general results of Bouchard's investigations are as follows. Among the substances secreted by the microbes are some which have an inhibitory action on them—that is to say, these products tend to retard the development, increase and characteristic action of the micro-organisms; other substances are favorable to their growth. These, however, only act indirectly by modifying the material upon which they grow (peptones, etc). Such products may be favorable or unfavorable for other microbes. Some organisms produce poisonous substances upon which depends their virulency. Amongst pathogenic microbes are some which secrete substances that confer upon animals inoculated with them an immunity against these particular germs; this they do not by their presence only, but by modifying the animal organism, so that it forms a less favorable pabulum for the development and growth of the bacteria, and causes the leucocytes to perform the process of diapedesis more rapidly, and to assume their functions as phagocytes more energetically. If an animal be inoculated with these substances, together with a pure culture of the same bacilli from which they were obtained, the disease runs a more rapid course, whilst its development will be delayed or prevented if the animal be inoculated a few days before the injection is made. If bacteria which act antagonistically towards one another be cultivated together in a test-tube, the soluble products of the "stronger" can be made to retard the development of the "weaker" organism. So that if an animal be inoculated with the products of metathesis of the "stronger" at the same time as the active principle of the "weaker," the action of the latter will be delayed and weakened. Some microbes appear to assist the action of others; these Bouchard terms "auxiliary microbes." By this means an animal may be infected with a disease which it would otherwise resist.—*Lancet*, December 27, 1890.

Antipyrin in Puerperal Fever.

Dr. Wm. McBeath says in the *Lancet*, November 22, 1890:

After parturition there is no condition more annoying and troublesome to the physician or disastrous to the patient than puerperal fever. Whether it occurs as the result of septicemia, from direct absorption

of putrid matter generated in the patient's own uterus, or from infection, the prognosis is always bad. The remedial measures generally used have been so often unsuccessful and are so unreliable, that any remedy or mode of treatment by which the great mortality from it can be materially lessened should be worthy of consideration and trial. Dr. McBeath has never noticed in any publication that antipyrin has been used with success in puerperal fever. In four cases in which during the past eighteen months he has prescribed it, it has acted almost as a specific. He gives details of the last case. The other three cases were almost the same, being characterized by the usual symptoms. They were treated in the same way, and all got better.

In the case he describes, a primipara, twenty-two years old, was attended by a midwife, and delivered of a male child on July 2, 1890. On July 7 the husband called in a medical man, who found her suffering with puerperal fever. He treated her in the usual way, with large doses of quinine, opium, hot linseed poultices and irrigation of the uterus with a solution of Condy's fluid. On July 10, as she was thought to be dying, Dr. McBeath was called in to see her in consultation, and found her pulse 140; temperature 103.5°; abdomen swollen, tender, and of the peculiar peaked shape, which we never see except in puerperal peritonitis; discharge scanty and fetid; milk almost gone; countenance anemic, and breath sweetish. She was also totally unable to move in bed. Dr. McBeath advised that the irrigation of the uterus and the hot poultices should be continued; and in addition, that antipyrin should be given in ten-grain doses every hour for six hours. In five hours the temperature had fallen below 100°. During the next twenty-four hours the antipyrin was given in the same dose every three hours, and after that the woman took another half-dozen powders, one every four hours. Thus in two days and a quarter she had taken eighteen powders of ten grains each, the temperature being kept down the whole time. At the end of this period her other symptoms had very much improved, the pain and tenderness had nearly gone, the swollen condition of the abdomen had disappeared, the appetite had returned, and she could move freely in bed. On the fourth day after Dr. McBeath saw her she had a sharp attack of diarrhœa, which sent up the temperature to 106°, but a mixture of soda, bismuth and opium soon relieved her and stopped it. She afterwards made a good recovery, no further bad symptoms supervening.

The symptoms in the other three cases were almost identical, except that none had diarrhœa after taking the antipyrin. The treatment was the same, and so were the results. In all there was immediate lowering of the temperature, followed by gradual amelioration of all the bad symptoms.

It will be noted that irrigation of the uterus and the hot linseed poultices were continued during the administration of the antipyrin, and, indeed, for a day or two afterwards; but it must be remembered that these had been used for several days before the drug was given, and that the patient was going from bad to worse. As auxiliaries no one would be justified in omitting them, but Dr. McBeath says he has never found irrigation of the uterus with an antiseptic solution and poulticing alone to cure puerperal fever. He feels satisfied that in antipyrin we have a remedy which, if given boldly and judiciously at the outset, will enable us to treat these cases with more hope of success. He has had such good results that he is anxious for others to try it. No doubt in certain cases a larger dose may be given at the beginning of the treatment; but in the case detailed above ten grains answered every useful purpose. Dr. McBeath generally orders each powder to be dissolved in two teaspoonfuls of brandy, and then a little cold water to be added, so as to make a draught of about an ounce and a half. Antipyrin, he thinks, acts as an antiseptic as well as an antipyretic, and it may possibly be of use in other cases of septicæmia or blood poisoning besides those arising after childbirth.

Massage in Eye Diseases.

In the *Meditzinskdiĕ Obozreniĕ*, Nos. 13 and 14, 1890, p. 59, Dr. W. K. Hirschberg draws attention to valuable services obtained by him from local massage in various ocular affections. In such cases where the eyeball should be subjected to the manipulations, he smears the surface of the eye with vaseline containing some yellow or white mercury (precipitate) or iodide of potassium, and, having placed a forefinger on the upper or lower eyelid, proceeds to quickly rub it against the eyeball in a radial or circular direction. In cases of massage limited to the eyelids alone, he makes friction either with a forefinger, or a tightly rolled cotton-wool

globule, commencing at the inner canthus and passing along a curved line down to the cheek (that is, correspondingly to the course of branches of the anterior facial vein, as suggested by Pfalz). In either case the sittings are repeated daily, lasting each time from 2 to 4 minutes. The treatment is especially recommended in, 1, *chronic forms of marginal blepharitis*, in milder or relatively recent cases of which all annoying symptoms (such as itching, sticking together of the eyelids, and so on) are said to disappear after four or five *séances*. As a rule, a complete cure ensues in from 10 to 15 days. The manipulations should always be preceded by a careful removal of dried crusts, which can be best effected by means of rubbing the margins with a piece of cotton-wool smeared with yellow mercurial salve. 2. *Phlyctenular conjunctivitis* where massage of the eyeball should be performed (after smearing the latter with a yellow mercurial or boric acid ointment). 3. *Follicular conjunctivitis*, in which Dr. Spaeth's plan should be preferred to all other methods; that is, the eyelid should be everted, the fornix conjunctivæ anointed with iodide of potassium salve, and the exposed fold itself subjected to rubbing with a forefinger's tip. Follicles disappear usually very quickly. 4. *Trachoma* of all stages, where a direct massage of exposed diseased areas may sometimes prove as successful as the treatment by cauterization (*e. g.*, with sulphate of copper), while being less disagreeable for the patient. 5. *Phlyctenular keratitis*. 6. *Corneal opacities*, remaining after keratitis, where the treatment is frequently followed by a marked improvement of vision, and that not only in recent cases, but sometimes even in inveterate ones. 7. *Pannus Trachomatosus* and *Scrophulosus*, in which massage of the eyeball (with white mercurial salve and atropia) often proves very beneficial. Of contra-indications, the author mentions the presence of inflammation or even simple irritation of the iris. In acute glaucoma he failed to obtain any amelioration, the manipulations carrying a vivid pain to the patient.

Unconscious Parturition in a Primipara.

A case of high obstetric and medico-legal interest is to be found in the *Archives de Tocologie* for November. Physiologically painless parturition is rare. Tarnier has related some cases, including one instance where a Canadian woman occasionally dropped a baby on the ground, at term, without noticing it. In Howard's case labor took two hours; the patient was reading a book till a quarter of an hour before the child was delivered, which event occurred after some straining, not sufficient to make her cry out. In Dr. Brunon's case, newly reported, a married woman, aged 22, had a troublesome cough one day shortly before term. The coughing was accompanied with lumbar pains, which increased. At 11 o'clock in the evening the patient tried to pass a motion. She sat over an hour in the closet, believing that her pains signified painful defecation. Then she went to bed. At half-past 1 o'clock she woke up feeling a desire to pass a motion, with lumbar pains such as she had felt before when constipated. As she rose to go to stool a smart lumbar pain occurred, and she felt something between her thighs. On handling it she found, much to her surprise, that it was the head of her first-born. She declared to Dr. Brunon that the pains were entirely lumbar, she had no colicky sensations, and none of the expulsive pains usually so severe, especially in primiparæ. The desire to defecate was strong, and she stated that the child might have been born into the pan of the closet without her recognizing the truth of her condition till the moment of its delivery. The patient was an intelligent, well-educated woman, free from any neurosis. This case proves that in the case of an inexperienced person an infant might be expelled into the water in the pan of a closet without any intention of infanticide on the part of the mother.—*British Medical Journal*, December 20, 1890.

Making Beef-tea.

The *Chemist and Druggist*, November 29, 1890, under the title, "Best Method of Making Beef Tea," makes the following statement:

Miss Mary Spanton, of the Hospital for Women and Children, gets a prize from the *Nursing Record* for the following directions: "Take 1 lb. of the leg of beef, to which, when minced, add 1 pint of cold water. Let stand for four hours; then put it into an earthenware vessel lightly covered over, and place it inside another vessel, or pan, filled with water, which, after coming to boiling-point, must be allowed to simmer

from four to six hours gently. This can be thickened if desired, and the doctor approves, with arrowroot, sago or rice, when the patient can take it, or varied by putting ½ lb. of mutton or veal to ½ lb. of beef, and flavored with celery."

[Any one who follows these directions will find that his beef-tea has no beef whatever in it. The "*this*" which "can be thickened," etc., is the *water* round the earthenware vessel. It is curious that this slip in the directions was not noticed by the *Nursing Record*, which gave the prize, or the *Chemist and Druggist* which recorded the award. Why any one should get a prize for re-hashing so ancient a method of making beef-tea, and the value of the method itself, it is not worth while to discuss.]

How to Apply Forceps.

In a paper in the *American Journal of Obstetrics*, December, 1890, Dr. Henry D. Fry, of Washington, describes what he thinks the best method of applying the obstetric forceps. He quotes a thesis on this subject written by Dr. Lepage, of Paris, who says the ideal method of extraction with forceps is to apply the instrument in such manner that during traction the fetal head is free to execute all the movements that would occur were the labor normal.

The proper application of the instrument, to attain this result, is:

1. To grasp the sides of the head with the blades;

2. To make traction in the axis of the pelvic canal; and

3. To secure mobility of the head during its passage.

This last indication is most important, but has been overlooked. The great advantage of the Tarnier forceps is due to the traction being independent of the grasp of the handle, the head is absolutely free to perform movements of flexion and extension.

With these facts established, Dr. Lepage proves that the above advantages are secured by applying the Tarnier forceps to the sides of the child's head when at or above the superior strait. He says it was during the year 1883 that Pinard first made his high applications after this method, and since the beginning of 1884 he has never employed them otherwise.

Dr. Fry sums up his opinion as to the application of the forceps as follows.

1. Anesthetize the patient and place her in proper position—buttocks well over the edge of the bed, and each limb supported by an assistant.

2. Ascertain the position of the head, introducing within the vagina two or three fingers, or, if necessary, the whole hand.

3. Apply the blades of a Hodge type of forceps to the sides of the head, with the concave edge directed towards the occiput.

If, for any reason, this cannot be accomplished, withdraw the instrument and substitute a Simpson, passing the blades to the sides of the pelvis. While making traction with this method, watch for anterior rotation of the occiput, and encourage it in some cases by reapplying the blades to better advantage.

4. Make every effort to secure aseptic conditions during the operation. The fingers, hands and forearms of the operator, the external genitalia and vagina of the patient, the instrument and the hands of the assistants, should be clean and aseptic.

On Oscillations in the Bodily Weight in Enteric Fever.

In the *Bolnitchnaia Gazeta Botkina*, Nos. 30 and 31, 1890, p. 747, Dr. Mikhail K. Zenetz, of Warsaw, publishes an important clinical contribution to changes in the bodily weight in typhoid fever, based on 384 carefully-studied typical cases. In each case the patient was weighed daily, between 9 and 10 A. M., all other clinical details possible being also registered from day to day, from his admission to his discharge or death. The following are the principal corollaries deduced by the author from his elaborate researches. 1. During the whole febrile stage of enteric fever the patient's weight steadily sinks, the average daily fall amounting to 0.6 per cent. (of the body's weight). During the first week of the disease the loss averages 0.8 per cent. a day; during the second, 0.7; during the third, 0.6; during the fourth, 0.5. In other words, as the disease advances, the relative loss in the weight decreases. 2. In uncomplicated cases, immediately after the onset of apyrexia, the weight begins to rise, the average daily increase amounting to 0.7 per cent. The largest relative gain occurs during the first week of convalescence, the rate gradually decreasing with each week. 3. In fatal cases the daily loss in the weight is usually very considerable, amounting fre-

quently to 3 per cent. 4. In such cases where a high fever is accompanied by sweats and diarrhœa, the weight sinks at an increased rate (up to 2 per cent. or even more a day). 5. Profound typhoid state (delirium, etc.) similarly increases the rate (up to 1 or 1.5 per cent. in a day). 6. The same holds true in regard to such complications as pleurisy, catarrhal or croupous pneumonia, parotiditis, otitis, etc. 7. An increase in the weight about the end of febrile stage (during lysis) points to a speedy advent of convalescence. 8. The retardation or arrest of increase in the weight after the onset of defervescence points to a nearing relapse or complication of this or that kind. 9. The daily losses in the weight above 1 per cent. justify a grave prognosis. 10. When such high losses coincide with a continuous and considerable acceleration of the pulse, the prognosis becomes almost absolutely hopeless. About the same conclusions have been reached by the author in regard to typhus fever. (See his *St. Petersburg Inaugural Dissertation*, 1887, with 103 cases.)

Hydrophobia in Egypt.

The Egypt correspondent of the *Lancet*, November 22, 1890, gives the following statements in regard to what he calls "hydrophobia in Cairo."

"Seven years ago," he says, "the streets of Cairo used to contain thousands of homeless dogs, and it was loosely believed that rabies was unknown among them. But the town has now been freed of pariahs, because they are no longer required as scavengers, and yet hydrophobia occasionally appears. The only two cases which have been known at the hospital during the last seven years have occurred during the past twelve months. A child arrived with cheek and lip disfigured by a bite from a dog four weeks before admission, there being no history of the dog being rabid. The wounds healed, but before the child left the hospital a hare-lip operation was done to prevent disfigurement. Two days after this operation the child developed hydrophobia, and died in three days' time. In the absence of inoculation experiments on rabbits, I suppose skeptics would affirm that this might be a case of tetanus, in spite of the presence of the clinical symptoms of hydrophobia. I may mention here that many cases are reported in Egypt of rabies and hydrophobia, which prove on investigation to be bites from healthy dogs, and some bitten individuals have been sent at public expense to the Pasteur Institute at Paris for prophylactic treatment.

"An interesting case, apparently of true hydrophobia, has just occurred at Kasrel-Aini Hospital. A young man-servant was sent up by his master with symptoms of exhaustion, great mental excitement, uncontrollable terror of draughts of air, sleeplessness and thirst. He made pitiable attempts to drink, and clutched the glass of water a few inches from his lips. He eventually allowed about half an ounce to be tilted between his lips, when he held the fluid several minutes in his mouth, seemed to swallow it, but then had a convulsion of throat and whole body, and hawked it up again with viscid saliva. He was treated with morphia injections and nutrient enemata, but twenty-four hours after admission he was dangerously maniacal, and had to be tied down in bed, and he eventually died six days and a half after he was first noticed to be ill. His previous history was that of an irritable, excitable person, but free from alcohol, hasheesh, or religious excitement. He denied that he had ever been bitten or scratched by any animal, and he had no traces of a bite on his body. His master's account is that eighteen months previously the boy had rescued a stray cat from a boar-hound who was playfully holding it on the ground. The cat was very frightened, and bit and scratched the boy through his clothes on the right thigh, but it is said that no mark was seen on the skin. If this was the cause of the disease, the long incubation is deserving of note, and it is the first time on record of a rabid cat in Egypt. The boar-hound was certainly not rabid, but there was no information about the future life of the cat. At the necropsy, twenty-one hours after death, the hands were blue and half clenched, the legs, but not the arms, were very stiff; the brain membranes were much congested, the cervical and dorsal membranes of the spinal cord were considerably congested, and the blood in the skull and body was dark and liquid, as in typhus. There was, as during life, redness of fauces and pharynx with great congestion of lungs, liver and kidneys; the heart was very firmly contracted, with no blood on the left side and a little black clot on the right.

"One of the arguments in favor of hydrophobia existing occasionally in Egypt is that the natives have a remedy for it dating from the old Arab physicians. It is a beetle of

the cantharides family, which causes the patient to urinate and evacuate blood, and it is believed that in the urine may be seen tiny effigies of a dog as large as a barley-corn."

Flexible Wire Stems for Stenosis of the Cervix.

In the *Medical Press*, November 26, 1890, Mr. Alexander Duke says of the value of the flexible spiral wire stem in the treatment of stenosis, that it is now some years since he published a description of this stem, now well known to gynecologists. Its principal use is to preserve the potency of the cervical canal after the operation of division of the os and cervix, commonly required as a cure for stenosis, giving rise to destructive dysmenorrhœa and sterility. He says that if one of the stems be introduced directly after this operation, it will not only prevent any union of the cut surface, but also, the subsequent contraction of the canal so commonly observed, and any tendency to excessive hemorrhage, by exercising a certain amount of pressure on the incised part.

These stems being self-retaining and requiring no vaginal support whatever, in addition or tampons of any kind can be worn by the patient when up and about, being flexible and short, cause no irritation; open at point and hollow, permitting free drainage, and easily kept clean while *in situ*, by syringing vagina daily during healing process, the water finding its way in and out of stem. His practice is to allow the instrument to remain till one "period" at least is over, subsequent to its introduction, or in other words, he allows the patient to menstruate through the stem, and he finds if this is done, there is no subsequent contraction of the canal observable years after the operation.

In cases thus treated, Mr. Duke has never had any complaint of a return of the symptoms existing before operation, nor has he had the slightest trouble, such as metritis, parametritis, cellulitis or septicemia.

The stems are easily introduced, the "duckbill" being the best speculum to facilitate this, and when once *in situ* they need not be interfered with until removal is considered desirable.

When Mr. Duke decides on using a stem that has been employed before, he takes the precaution to let it lie in boiling solution of creolin for a few minutes, and then fills the stem with either boric acid or iodoform, which does not add any difficulty to its introduction, the "introducer" penetrating the powder in the stem.

Mr. Duke has also found these stems useful as a drain in cases of chronic endometritis, and as a mechanical agent in plethoric amenorrhœa, or in those cases where the usual routine treatment to stimulate uterine action has failed.

The Teeth in Epilepsy.

Speaking of the importance of examination of the teeth in epilepsy, the *Lancet*, December 27, 1890, says that Dr. Bakowski mentions in the *Przeglad Lekarski* an instructive case of epilepsy occurring in a young Jewess. It had been going on for nine months, and latterly the fits had become more frequent, there being several every day. Bromide of potassium, quinine, arsenic and asafœtida had been given without any effect. Finally, although there was no complaint of toothache, it was decided to examine the mouth. Two teeth were found to be carious—the first upper molar on the right and the first lower molar on the left side. These were extracted, with the result that the fits entirely ceased and did not return, though the patient was under observation for six months subsequently. Upon being closely questioned the girl remembered that before the fits commenced she had had some unpleasant sensations in the affected teeth, but nothing that could be described as pain.

Southern California as a Health Resort.

Charles Dudley Warner says, in an article in *Harper's Monthly*, January, 1891, that there are many people in the United States who could prolong life by moving to Southern California. There are many who would find life easier there by reason of the climate, and because out-door labor is more agreeable there the year through; many who have to fight the weather and a niggardly soil for existence could there have pretty little homes with less expense of money and labor. It is well that people for whom this is true should know it. It need not influence those who are already well placed to try the fortune of a distant country and new associations.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

MEDICAL EXAMINERS AND MEDICAL EDUCATION.

A bill (published at Page 141, of this number of the MEDICAL AND SURGICAL REPORTER), which is intended to regulate medical education in Pennsylvania, has been introduced in the Legislature at Harrisburg by Mr. Brookes, of Philadelphia. This bill provides for the appointment of a Board composed of three eclectics, three homœopaths, and three persons spoken of in the bill as "allopaths." The bill makes it illegal for any medical school in this State to give degrees to students who have not gone through what is spoken of as four years' study, which shall include three courses of lectures, or to admit as students persons who have failed to meet certain requirements of preliminary examination to be prescribed by the Board. To this is added that the Board shall act as a sort of Police Board to report the failure on the part of any medical school to obey the provisions of the law, such failure being punishable by a heavy fine.

There are several unfortunate things about this bill. In the first place, what it aims at in regard to medical education might—if constitutional—be secured quite as well by a simple enactment, without the intervention of any Board at all; in the second place—considering that in Pennsylvania about four-fifths of the physicians belong to the regular portion of the profession, and that one-fifth are divided between the Eclectics and the Homœopaths, and that there are in this State five medical colleges conducted by the regular profession, while there is only one Homœopathic school and not one Eclectic school—it is obviously unequal that a Board which would be practically a Board of censors upon the medical schools, should contain six representatives of the one medical school as against three representatives of the five schools. More than that, we believe that the selection of a Board of this kind is absolutely impracticable. The members of the regular profession are not allopaths; and no one who knows anything about the use of correct terms thinks they are; and it is improbable that three men of any standing in the profession could be induced to become a part of a Board containing six members who willingly bear an exclusive title, or to accept the imposition of an exclusive title upon themselves—facts and principles would both prevent this.

There seems to be little hope that those who, in this matter, claim to represent the body of so-called homœopathic physicians, will abate a particle of their seeming distrust of those who desire that Pennsylvania shall be put on an equal footing with the best and most intelligent States in the country, by providing for a Board of Medical Examiners, who shall represent directly the State and the community, and shall simply determine the fitness of persons to whom are to be entrusted the lives and the health

of the citizens of this State. Some of us who desire this, deprecate most deeply that what we believe to be a desirable result should be imperilled by sectarian differences. We want the State of Pennsylvania to be placed on the very highest level in this matter. We naturally believe that that part of the profession to which we belong is the one which is most in accord with reason, but we have sufficient confidence in the intelligence of the Governor and of our fellow-citizens to be willing to have a bill passed which shall say nothing whatsoever about the character of the persons to be appointed on the examining board, or direct how they shall be chosen. This we say with full knowledge that the present Governor is supposed to have long been under the care of homœopathic physicians, and to be in some sense an adherent of that school; for he is quite as well known to be a man of integrity and courage.

The cause for which we strive we believe to be so just an one, and so sure of ultimate success, that we are quite willing to entrust the details of its accomplishment to an honorable man and have no doubt that the issue would be such as to be approved by all honorable men.

The REPORTER is opposed to the bill referred to above, for the reason that it is, we believe, in the first place, needless; in the second place, impracticable; in the third place, unfair in its provisions, and perhaps unconstitutional. We support heartily the bill published in the REPORTER, January 10, 1891, because we believe it is in the interest of our fellow-citizens, and that it is thoroughly practicable. As we have already said there are certain details of the bill which are not precisely what we would have wished; but its passage would do much, we believe, to promote the interest of medical science and the good of the community.

LEGAL RESTRAINT OF INEBRIATES.

The REPORTER has at different times given considerable space to the claims and arguments of those who are convinced that the tendency to excessive indulgence in alcoholic stimulants is to be regarded and treated as a disease condition, and this partly for fairness' sake and partly because it holds the opinion that in many cases the tendency is one which can best be combatted if regarded from a physical and not from an exclusively moral standpoint. But it is sometimes far easier to suggest a general principle in keeping with which to arrange a plan of treatment than it is to specify the details of such a plan. The truth of this fact appears when we reflect upon a discussion which took place before the Medical Jurisprudence Society of Philadelphia, January 13. Dr. Dercum, who opened the discussion, spoke of the change of general and professional opinion in regard to the treatment of inebriates and claimed that the inebriate should be treated as a sick man, and his condition should be considered the same as in a case of insanity. The State of Pennsylvania, he said, places no control over the inebriate until he is practically beyond recovery, and what is needed is a system of special asylums maintained by the State, in a manner similar to insane hospitals, with special laws and regulations. Legislation should deal with inebriates in general, no matter what the narcotic used may be, whether alcohol, opium or chloral. He thought, also, that druggists should be held to a strict account, as he had known where a prescription once given had been renewed for years.

John A. Clark, Esq., presented some of the difficulties from a legal standpoint of carrying out the plan which seemed to be approved by physicians. He doubted whether an inebriate, on the certificate of two physicians, could be sent to an insane asylum. In the State of Wisconsin, he said, it was tried to control such persons by law, but the Supreme Court decided against the constitutionality of such proceedings.

Dr. E. N. Brush, of the Pennsylvania Hospital for the Insane, who has had all

kinds of inebriates to care for, would classify them as those who were drunkards by reason of certain disturbed, unbalanced nervous conditions; those who were drunkards through viciousness, and those who were the victims of disease. The trouble in dealing with them, he thinks, is the same as in cases of insanity, where persons are allowed to go on without treatment because they are not sufficiently insane to warrant a certificate being given. In New York, he said, a man cannot be legally held unless he is dangerous to himself or those around him, and, like Dr. Dercum, he thought that men, unfortunately, were allowed to go on until beyond the hope of recovery.

Thus the discussion ended without the proposition of any plan which appeared feasible to both lawyers and physicians. This does not signify that the endeavor after a feasible plan should be abandoned; for, if the State should extend a supervising and controlling care over individuals for their own good or for the general welfare, it is desirable that all who are interested in public questions should continue to inquire what may properly be done to restrict the evil consequences of the drink habit. The question discussed by the Philadelphia Medical Jurisprudence Society at its last meeting is—as one of our lay contemporaries calls it—a "knotty one;" but time and patience may get through or get round these knots.

BARKING COUGH OF PUBERTY.

It is a well-recognized fact that cough does not necessarily imply an affection of the lungs or bronchial tubes. Coughing is a reflex act, in which the lungs are filled with air by a deep inspiration; the glottis is then completely closed, but it opens suddenly under the pressure of a forcible expiration, by which a column of air is driven through the upper respiratory passages. The apparent impulse to cough is usually transmitted by the superior laryngeal nerve, but any one of the other nine branches of the pneumogastric may carry it. Almost every one, for example, has seen instances of cough excited by examining the ear, or by foreign bodies in the auditory canal. Another variety of cough, however, which is entitled to be considered distinct, is described by Sir Andrew Clark, in the *Lancet* for December 20, 1890. The paroxysms which characterize the cough in question are well illustrated in the first case reported by Dr. Clark. They consisted of a close succession of loud, dry, clanging, convulsive coughs, varying in intensity and duration, broken into irregular bars and phrases, resembling at one time the barking and at another the howling of a dog. During the continuance of the paroxysm the patient appeared to be much distressed; his face was swollen and faintly livid; the eyeballs became prominent and congested; the body, bent forward, was shaken by the violence of the coughing, and the hands, which were crossed upon the chest, convulsively clutched his clothes. At the close of the paroxysm the patient appeared to be a little dazed and was somewhat giddy. He recovered in a few minutes, passed a quantity of limpid urine, and the storm was at an end.

The attacks are not always as severe as in the case just referred to; they vary greatly in severity. The age at which patients are affected is that of puberty, generally from the thirteenth to the sixteenth year. More girls are affected than boys. The general health suffers but little, and there are no physical signs on the side of the lungs. The patients are generally, though not always, of nervous habit and heredity, and most of those seen by Dr. Clark were over-fed; in addition to ordinary meals there were frequent "interludes" of different kinds of food, preserved for the most part, and alcoholic beverages of some sort were freely administered. The course of the affection, according to Dr. Clark, though usually tedious and sometimes prolonged, has ended eventually in complete recovery.

As to the pathology of this convulsive

cough of puberty, Dr. Clark seems to think that the seat of the disease is in the spinal ganglia which have recently been shown to exercise a marked control over respiratory movements. The condition of unstable equilibrium and hyper-excitability which characterize the organism at the period of sex evolution account for the development of the cough at this time, especially when one bears in mind that the larynx is one of the principal seats of the changes which take place at puberty. The neurotic tendencies of the patients, and the absence of any local changes adequate to the explanation of the malady, warrant the belief that it is of nervous origin.

Regarding the treatment of the affection, Dr. Clark says that improvement has almost invariably followed the enforcement of a simple but liberal dietary, arranged in three, or at most four, meals a day; abstinence from alcohol; cold or tepid sponging; warm but not too warm clothing; active out-door exercise, early hours and general discipline. Of local applications, only two have done good service. The first is glycerine of borax with oxychlorate of bismuth and morphia, and the second is the same combination with the substitution of cocaine (ten per cent.) for morphia. These applications should be brushed over the whole interior of the throat after each meal, and also at bed-time. In using cocaine, care must be taken in its application to the larynx, which is sometimes provoked by it into dangerous spasm. Only two internal remedies have been found of service, one is syrup of bromide of quinine and iron, with small doses of arsenic; and the other is a pill of reduced iron, valerianate of zinc, belladonna and nux vomica. These pills must be given in slowly increased dose until the physiological effects of the belladonna become apparent; and then, slightly diminished, the amount of belladonna administered should be maintained at that level for some time. Dr. Clark does not approve of the long sea voyage in the treatment of this affection.

Dr. Clark has the happy faculty of putting an old truth in a fresh light, and by a well-chosen name giving definiteness and precision to what many have seen before, but have not closely studied. The affection he describes is not new, and he does not claim that it is; but he is none the less entitled to great credit for his admirably clear description of it, and for the valuable suggestions as to its treatment.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

A MANUAL OF MODERN SURGERY. An Exposition of the Accepted Doctrines and Approved Operative Procedures of the Present Time. For the Use of Students and Practitioners. By John B. Roberts, A. M., M. D., Professor of Surgery in the Woman's Medical College of Pennsylvania, etc. With five hundred and one illustrations. 8vo, pp. xvi, 800. Philadelphia: Lea Brothers & Co., 1890.

Dr. Roberts has set himself the task of writing a condensed treatise on modern surgery. He has aimed to have the work practical, and to this end has avoided the discussion of theories, historical questions and traditional views and operations.

The book is divided into two parts. Part I includes general surgical pathology, or principles of surgery. Under this heading the author discusses inflammation, erysipelas and septic processes, scrofula and tuberculosis, syphilis, rickets, tumors, wounds and shock, mode of repair and treatment of wounds, practical surgery and anæsthesia, operative surgery, and plastic or reparative surgery. Turning to anæsthesia, as a subject which has excited world-wide interest, especially during the past year, we notice that the author appears to have been very little influenced by the testimony indicating that chloroform is not as dangerous as it is generally believed to be in the northern and western part of the United States. Dr. Roberts declares that chloroform is much more dangerous than ether, and that "this is a sufficient cause for the abolition of its (chloform's) use." The advantages claimed for chloroform over ether are attributed to improper methods of giving the latter. The author's method is to give the patient a hypodermic injection of morphine and atropine about fifteen minutes before inhalation is begun, and then to give the ether in concentrated form from a napkin covered by a towel. "When inhalation is once fairly begun the ether cloth should never be removed from the face unless spasm of respiration or actual vomiting necessitates its temporary withdrawal." Quite apart from the choice of ether or chloroform as an anæsthetic, what might be termed the "suffocative" method of administering ether seems to be more saving of the time and patience of the surgeon than of the comfort of the patient.

Part II is devoted to Special Surgical Pathology or Practice of Surgery. The author's descriptions of resection of the intestine and of intestinal anastomasis

are especially good, and the illustrations well-chosen and very helpful to an understanding of the operations. The definition of amputation is a strange blunder: "By amputation is meant the removal of a locomotor extremity of the body;" the upper extremity, however, is included, and description of its operative removal given.

The author is to be congratulated upon keeping so closely to his purpose to make the book modern in its teaching and practical in its bearing. While the teaching on some points might be criticised as too dogmatic, it is in the main sound, and it is presented with admirable clearness and brevity. The illustrations seem to have been selected strictly with a view to their utility, and are certainly well-chosen. The text is remarkably free from typographical errors for a first edition. Both author and publisher have every reason to feel proud of its handsome appearance. We can cordially recommend it to our readers as one of the best books for students which has appeared in the English language.

ESSENTIALS OF THE DISEASES OF CHILDREN. Arranged in the form of questions and answers, prepared especially for students of medicine. By William M. Powell, M. D., Physician to the Clinic for Diseases of Children in the Hospital of the University of Pennsylvania, etc. Small 8vo, pp. 214. Philadelphia: W. B. Saunders, 1890. Price, $1.00.

Dr. Powell has succeeded in compiling, from a number of the standard works on diseases of children, a very creditable compend, which forms No. 15, in Saunder's series. Most attention is given to symptomatology and treatment. In both the author follows Goodhart and Starr very closely. The descriptions are clear, and for the most part accurate and trustworthy as well. In speaking of the treatment of *tinea tonsurans*, Dr. Powell gives Dr. Harrison's treatment incorrectly, the principal ingredient in the formula, bichloride of mercury, being omitted altogether. Dr. Harrison recommended two solutions, the first consisting of liquor potassæ and iodide of potash, and the second of sweet spirit of nitre and bichloride of mercury. After the first had been well rubbed into the scalp, the second was to be applied. The object sought to be obtained was the production of biniodide of mercury, from the reaction between the bichloride of mercury and the iodide of potash, and the bringing of this biniodide into contact with the fungus. But there is some doubt whether or not the biniodide results from the reaction. It may be of interest to mention here that Dr. Harrison thinks he has found an ointment, composed of carbolic acid (gr. xxiv), caustic potash (gr. ix), and lanolin and oil of theobroma (of each ℥ ss), much better than the two solutions originally recommended.

The book fulfills a useful purpose, and may well find a place among others of this excellent series of compends.

Literary Notes.

—The *Medicinische Neuigkeiten* commences its forty-first year in 1891. It will hereafter be published by Jos. Ant. Finsterlin in Munich. Prof. Martin continues to be its editor. Under his long connection with this journal it has acquired a deserved popularity, especially among practical physicians in Germany.

Correspondence.

Wound of Rectum.

To the Editor.

Sir: Thinking it might be of interest to some readers of the Medical and Surgical Reporter, I write concerning a wound sustained by Mr. A., living some distance in the country. While feeding his stock after dark, he accidentally got astraddle of the horn of an ox, and the animal in raising its head caught the man on the point of its horn with such force as to penetrate the left ischio-rectal region two inches to the left of the anal orifice, the horn going through the left wall of the rectum, three inches above, abrading the opposite internal rectal wall.

I arrived at night and was in doubt as to the best procedure at the time; so I used temporary means and dressings until next day, injecting per rectum an antiseptic fluid, which found external exit through the ischio-rectal wound. I saw also that the bowels were well emptied, thereafter keeping them closed by opiates for the period of six days. Not having in my books anything treating especially of such wounds, I next day chloroformed the patient and sewed up the rectal wound internally with catgut, using a rectal speculum and a slightly-bent perineum needle, with handle. I applied a firm pad over the external seat of the wound, and instructed the patient to keep on the right side, especially when defecating. As I had had the sphincter ani to contend with, I was in doubt as to the success of my treatment. I noticed but little defecation of a liquid character from the wound after the first week. In one month's time the patient came to my office comparatively well.

Yours truly,

W. H. Lewis, M. D.

Birnamwood, Wis.

Notes and Comments.

State Board of Medical Education.

An Act to Establish a State Board of Medical Education, to Define the Powers and Duties of such Board, and to make an Appropriation therefor.

Section 1. Be it enacted by the Senate and House of Representatives of the Commonwealth of Pennsylvania in General Assembly met and it is hereby enacted by the authority of the same: That within three

months after the passage of this Act, the Governor shall appoint by and with the advice and consent of the Senate, a State Board of Medical Education consisting of nine members, physicians in good standing, citizens of this Commonwealth, three of whom shall serve for two years, three for four years and three for six years, and thereafter, biennially, there shall be appointed in the same manner three members of the said Board, one from each school of practice, as provided in this Section, to serve for six years in the place of those whose term shall have expired. They shall be graduates of some legally chartered medical college, or university having the power to confer medical degrees, who shall have practiced medicine or surgery for a period of not less than five years. Provided: That in the appointment of said Board the members shall be chosen equally from lists of names each list containing the names of ten registered physicians submitted by the State Medical Societies of the Commonwealth of Pennsylvania, to the intent that the three systems of medicine, *i. e.*, homœopathic, allopathic and eclectic be equally represented thereon, and provided further: That no two members shall be residents of the same county. In default of the submission of such lists, the appointments shall be made by the Governor at his discretion from among the registered physicians of the Commonwealth having the qualifications specified in this section.

Every appointment to fill a vacancy, or vacancies, in the said Board, shall be for the unexpired term, and the said vacancy, or vacancies, shall be filled by the Governor within sixty days after notification of the same, in accordance with the provisions hereinbefore stated; and he shall have power to remove any member of said Board for criminal, scandalous or dishonorable conduct.

SECT. 2. The said Board shall be known by the name and style of THE STATE BOARD OF MEDICAL EDUCATION OF THE COMMONWEALTH OF PENNSYLVANIA, and shall have a common seal, and may make and adopt all necessary rules and regulations and by-laws, not inconsistent with the Constitution and laws of this Commonwealth, or of the United States, and shall have power to locate and maintain an office for the transaction of its business.

Five members of said Board shall constitute a quorum.

SECT. 3. The Board shall meet at least twice each year, at such times and places as they may determine upon after the first meeting, which shall be held within sixty days after their appointment at such time and place as the Governor may direct, at which time, and annually thereafter, they shall organize by the election from their own number, of a President and a Secretary who shall also act as Treasurer. Provided: That the President and Secretary are not of the same school of medicine.

SECT. 4. No member of the Board except the Secretary shall, as such, receive any salary; but the actual traveling and other expenses of any member, while engaged in the actual duties of the Board, shall be allowed and paid on presentation to, and approval by, the Auditor-General, of an itemized account with vouchers annexed.

SECT. 5. It shall be the duty of said Board of Medical Education, to make all regulations as to the extent and character of the preliminary education, which shall be required of all students of medicine, and notify the dean of each medical college of the same. Any change in the standard required, must be announced by the Board at least one year prior to going into effect.

SECT. 6. The Board of Medical Education shall fix the minimum curriculum, and length of course of studies requisite to graduation. Provided: That the course shall not be less than four years, which shall include three annual terms of lectures. The Board shall delegate one or more of their number, who from time to time shall make an inspection of the methods of instruction employed, and the facilities for teaching, in each such medical college, and annually report the same to the Board.

SECT. 7. It shall be the duty of the Board to issue, under seal, to each graduate of such medical colleges as upon evidence of the dean and the secretary, or registrar of the same, shall have conformed to the requirements of the Board as herein before provided, a certificate duly setting forth such facts. Such certificate shall entitle said graduate, to register in any county of the State, in accordance with the act entitled, "An Act to provide for the registration of all practitioners of medicine and surgery" approved June 8, Anno Domini 1881.

The fee for such certificate shall not exceed two dollars.

A similiar certificate may be granted to graduates of medical colleges of other States,

who may desire to practice medicine or surgery in this State, provided that such colleges stand approved by the Board of Medical Education of this Commonwealth as maintaining a standard in every respect, preliminary and final, equal to that required of the medical colleges within this Commonwealth.

The fee for such certificate shall not exceed five dollars.

Graduates of colleges having a lower standard than that required by the Board of Medical Education of this Commonwealth, may receive the certificate of the Board upon a satisfactory examination before said Board. Such examination shall be in writing, and shall apply to the preliminary education, as well as the medical knowledge of the applicant. Provided: That all questions pertaining to materia medica, and therapeutics, shall be propounded and acted upon, by members of the Board of the same school of medicine with the applicant.

The fee for each such examination shall be twenty dollars.

All examination papers shall be kept upon file, and open to inspection, for a period of two years in the office of the Board.

SECT. 8. If upon investigation the Board of Medical Education discovers, that after the passage of this act, any medical college within this Commonwealth, has granted the degree of doctor of medicine to any person, or persons, deficient in respect to either the aforementioned preliminary or final educational requirements, or that any medical college within this Commonwealth, has conferred the degree of doctor of medicine upon any person, or persons, without having passed a final examination, it shall be the duty of the Board to notify the dean of said college of such fact, and proceed against such college for such infringement of the law. The penalty for a first offense, shall be a fine of not less than two hundred nor more than one thousand dollars. For a second offense, a fine of one thousand dollars shall be imposed, and the certificate of the Board of Medical Education shall be withheld from future graduates of said college, except upon examination before said Board, as provided in Section 7 of this act. In case of conviction for a third offense, the charter of such college shall be annulled.

SECT. 9. The Board of Medical Education is hereby authorized and empowered, to bring suit for the collection of such fines and imposition of such penalties, in the courts of the county wherein such college may be located.

All fees and fines collected by said Board shall be paid to the State Treasurer.

SECT. 10. After the first day of June, 1892, no physician shall be permitted to register in any county of this Commonwealth except upon presentation of a certificate as provided for in Section 7 of this Act, whereupon he or she shall be entitled, upon the payment of one dollar, to be duly registered in the office of the Prothonotary of the Court of Common Pleas in the said county; and any persons violating the provisions of this Act shall be guilty of a misdemeanor, and, upon conviction thereof in the Court of Quarter Sessions of the county where the offense shall have been committed, shall pay a fine of not less than fifty, nor more than five hundred dollars for each offense.

SECT. 11. Nothing in this Act shall apply to commissioned medical officers of the United States army or navy or of the United States marine hospital service, nor to any member of the house or resident staff of any legally chartered medical college or university or hospital during his or her term of service therein, nor to physicians of other States meeting duly registered physicians of this State in consultation, nor to those practicing denistry exclusively, nor in any manner whatever prevent or interfere with the dispensing and sale of medicines or medical appliances by apothecaries or pharmacists, and nothing in this Act shall be construed to prohibit the practice of medicine and surgery within this Commonwealth by any practitioner who shall have been duly registered before the first day of February, 1892, according to the terms of the Act entitled "An Act to provide for the Registration of all Practitioners in Medicine and Surgery" approved the 8th day of June, Anno Domini 1881.

SECT. 12. The Board shall make to the Governor, on or before the first day of December of each year, a full report of the work of the Board for the year.

SECT. 13. For the purpose of this Act, the words "practice of medicine or surgery" shall mean to treat, or attend, any person for money, gift or reward.

SECT. 14. The sum of two thousand dollars is hereby appropriated, to meet the necessary and legitimate expenses of the said Board.

SECT. 15. Section 4 of an Act entitled

"An Act to provide for the Registration of all practitioners of Medicine and Surgery" approved the eighth day of June, Anno Domini 1881, is hereby repealed.

Endorsing Medical Examiners' Bill.

At an informal meeting of a number of well-known physicians, held in Philadelphia this week the bill to establish a State Board of Medical Examiners and Licensers, prepared by the Committee on Legislation of the State Medical Society and presented to the House of Representatives last week by Representative Riter, was carefully considered. It was concluded that the bill is in the interest of public welfare and a resolution was adopted that "the medical profession should give its heartiest support to the bill."

Those present at the meeting were: Drs. S. Weir Mitchell, J. M. DaCosta, William Pepper, William W. Keen, William H. Waugh, J. W. Holland, James Tyson, Clara Marshall, James W. Walk, Charles W. Dulles, Hobart A. Hare, Edward Jackson, Edward H. Montgomery, William H. Parish, Horatio C. Wood, Lawrence F. Flick and John B. Roberts.

Philadelphia Polyclinic.

At the annual meeting of the Philadelphia Polyclinic and College for Graduates in Medicine, held at its building, Lombard, above Eighteenth street, January 12, 1891, the Trustees reported that the past year had been one of great activity in the institution and continued. The occupancy of the new building on December 29, 1890, was made possible by the generous contributions that have been received during the past two and one-half years. The furniture required for eleven rooms, the entire outfit of the apothecary shop, the electrical apparatus for the Nervous Department, and the outfits for the Orthopedic and Photographic Departments, are the most important of these contributions.

During the year just closed four free beds have been endowed upon the progressive endowment plan, and an agreement has been entered into with the Nurses' Beneficial Association whereby any member taken sick in the pursuit of her calling is cared for, free of cost, in a room perpetually endowed by the association.

There were, during the past year, a greater number of pupils than ever in the college department, and more patients in the hospital. The new building will provide accommodations in its four wards for about forty-three patients and private rooms for eight to twelve patients.

The Board of Public Charities has recommended the Legislature of the State to make an appropriation of $40,000, which is a recognition by that discerning body of the importance and needs of the institution.

Three new chairs have been created in the departments of surgery, diseases of the eye and diseases of the throat and nose, to be occupied respectively by Dr. John B. Deaver, Dr. S. D. Risley and Dr. Arthur W. Watson, who have been elected Professors.

The Copyright Bill.

Speaking of some of the effects that will follow the passage of the International Copyright bill, the Editor of *Harper's Weekly* says: The passage of the International Copyright bill by the House of Representatives is an event of great importance. It will pass the Senate probably without delay, and the President has already expressed his approval of it. This is the final success of an intermittent effort of more than fifty years, during which the most eminent American statesman have advocated the measure, and projects of law and treaties have been carefully discussed. The opposing forces have been of various kinds. Chiefly they have been the general conviction that literary property is different in kind from other property, and that the law has acknowledged the difference; that the measure would heighten the prices of books; and that it was not for the interest of American printers and publishers.

The reciprocity of action upon the part of other governments which the act contemplates will follow its passage, and then the results of the measure will appear. Its effect is, in brief, to extend the author's copyright to all countries in which his work is sold, without injury to the interest of the local manufacturer and publisher. It removes from a great industry the imputation of unfairness, and throws off the burden which has hitherto oppressed literary effort in this country. The bill is emphatically a measure of fair play, which will inevitably promote a friendly feeling between all the countries which it affects. In the first week of the session the House has led the way in

legislation which honest men in every country will approve. [It is to be feared that *Harper's Weekly* has been too sanguine about the passage of a bill the chief interest of which is moral.]

Bone Grafting.

Mr. A. G. Miller, in the *Lancet* for September 20, reports the history of a case in which he used decalcified-bone chips successfully to fill up a large cavity in the head of the tibia. A piece of the rib of an ox was used, being first scraped and then decalcified in a weak solution of hydrochloric acid. After cleansing by pressure, it was placed for forty-eight hours in a carbolic-acid solution, one to twenty, then removed, and cut into small pieces. During the scraping out of the cavity in the knee, preparatory to the grafting, a number of small pieces of bone were removed. These were placed in a solution of boric acid for use later in the operation. The cavity was then stuffed with the decalcified-bone shavings, the pieces of fresh bone being added last. The cavity thus filled was about two inches in diameter. Granulation and healing took place rapidly; the only pieces of bone that became necrosed were from the patient's own body. Mr. Miller is convinced, from his observation of this case, that the healing of large bone cavities, the result of injury or disease, is greatly facilitated by stuffing them with decalcified-bone chips, that these are superior to fresh bone, and that fresh bone not only is of no use, but actually hinders the process of granulation. *New York Medical Journal*, November 29, 1890.

Public Health in New Jersey.

In the annual message to the Legislature by the Governor of New Jersey, attention is called to the gradual increase of typhoid fever in most of the cities of the States. This is accepted by sanitary authorities as indicating inadequate sanitary administration. To protect the people from this and other pathogenic diseases, the Governor says there should be systematic house inspection, and the removal of waste products in cities should be systematically and rigidly enforced. Attention is called to the Tenement-house law, in force in New York, as being one which would aid in securing more healthful homes for the people. It is stated that the use of wells and cesspools in cities of over five thousand inhabitants is generally such that there should be prohibitory or strong legislative regulations.

The message contains a recommendation that summary control should be given to the State Board of Health or some proper authority over streams of potable waters so as to prevent their pollution, and further recommends that the impounding of waters for artificial lakes should be restrained by law, as such acts cause partial stagnation, and thereby render the locality subject to disease; also power be given to the State Board to act in cases of local nuisance where the authorities of the district fail to act.

The Relief of Pruritus.

The *Medical Record*, December 20, 1890, says:

Itching is of various kinds, and depends upon a great variety of cutaneous lesions. In some instances there are no eruptive features connected with sensation, and we have an independent disease without eruption, excepting such as continual scratching will produce. In the *Record* of October 18, we published a scientific study of "The Sensation of Itching" from the pen of Dr. Bronson, which points out the reasons why people itch. What will stop the itching is a question which is of equal interest both to the sufferer from pruritis and the physician called upon to relieve it.

Dr. Bronson tells us, among other things, that scratching relieves itching by directing the excitation into freer channels of sensation sometimes, especially when severe, substituting for the pruritis either painful or voluptuous sensations. It is scarcely ever necessary for the physician to prescribe this means of relief. It has been a household remedy for ages, and the infant has mastered its application before it graduates from the cradle. More frequently we have to order our patients not to scratch, because the relief attending the act is evanescent, and the damage done to the skin in a moment may take weeks or months to repair.

It is needless to say that this injunction can frequently not be enforced by any means short of the straight jacket.

Fortunately there are a few, out of the many recommended, drugs for the relief of pruritus, which have a more or less pronounced and lasting effect.

Menthol is not a new remedy in this sense, but it has of late received consider-

able attention. Dubreuil and Archambault have studied its effects in a variety of pruriginous affections, and find that with it they can succeed in calming itching of whatever nature it may be, but that it has its greatest effect in those cases where scratching provokes or keeps up the lesion of the skin and the pruritus. This is particularly true of urticaria, certain eczemas, and the pruritus following scabies after the itch-mites have been destroyed.

In urticaria a ten per cent. solution in alcohol or almond-oil can be employed, and in the acute and subacute forms is said to be capable of bringing about a speedy cure. For itching eczemas a five to ten per cent. solution in oil may be used, or from two to five per cent. of menthol may be added to oxide of zinc ointment. Upon excoriated surfaces and mucous membranes, care must be exercised not to use too strong applications, as a disagreeable sensation of burning may be determined, and for such parts an oily rather than an alcoholic solution should be chosen. Again, applications should not be made to the whole surface at once, since the sensation of cold which accompanies the anæsthetic action is in some cases extremely disagreeable.

In pruritus ani, perineal and genito-crural eczema, the results of treatment by menthol are said to be very favorable. We must not confound pruritus, as a symptom of numerous cutaneous diseases, with pruritus, an independent disease of nervous origin. In the former the underlying skin affection must be treated in an appropriate way, while anti-pruritics are relied upon to secure as much relief as possible.

Use of the Obstetrical Department of the Philadelphia Hospital for Teaching.

At a meeting of the Board of Charities and Correction, January 12, a committee appointed to consider the application of Dr. B. C. Hirst, one of the obstetricians to the Hospital, for permission to use the obstetrical department of the Philadelphia Hospital for the purpose of instruction to students, submitted an answer, in which they said they were fully aware of the importance of furnishing means for the education of physicians by the use of the hospital; but declined to approve of Dr. Hirst's proposition.

In face of the assurance that the possibility of infection was excluded, they said there was a possibility that proper precautions might be disregarded. The answer of the committee also alluded to the position taken by the late Miss Fisher, head nurse of the hospital, who had said that such a use of the department should not be permitted on any terms while she was living, and stated that the same opposition was felt by the present head nurse.

They also said if they felt bound to protect a corpse from examination in the cause of science, could they, with propriety, compel a living woman to submit to such exposure as is inevitable in the proposed scheme as the price of admission to a public hospital? They, therefore, declined the request, and put their answer on record for the information of their successors.

Nothing New Under the Sun.

The *Edinburgh Medical Journal*, December, 1890, says that it is curious to find that something like the present-day theories of a struggle between the microbes and leucocytes must have been in vogue more than a century ago, otherwise this bit of satirical burlesque could scarcely have been written and played.

Persons—The Devil as Hellebore, President of the College; Dr. Last, a new Licentiate; other Doctors and Pupils.

Hel. . . . Proceed we now to the lecture! Brethren and students, I am going to open to you some notable discoveries that I have made respecting the source or primary cause of all distempers incidental to the human machine. And these, brethren, I attribute to certain animalculæ of piscatory entities, that insinuate themselves through the pores into the blood, and in that fluid sport, toss and tumble about, like mackerel or cod-fish in the great deep. And to convince you that this is not a mere *gratis dictum*, an hypothesis only, I will give you demonstrative proof. Bring hither the microscope!

Enter a SERVANT *with a microscope.*

Dr. Last, regard this receiver. Take a peep.

Last.—Where?

Hel.—There. Those two yellow drops there were drawn from a subject afflicted with the jaundice.—Well, what d'ye see?

Last.—Some little creatures like yellow flies, that are hopping and skipping about.

Hel.—Right. Those yellow flies give the tinge to the skin, and undoubtedly cause the disease. And now for the cure! I administer to every patient the two-and-fiftieth part of a scruple of the ovaria or eggs of the spider; these are thrown by the digestive powers into the secretory, there separated from the alimentary, and then precipitated into the circulatory, where finding a proper nidus or nest, they quit their torbid state, and vivify, and upon vivification, discerning the flies, their natural food, they immediately fall foul of them, extirpate the race out of the blood, and restore the patient to health.

Last.—And what becomes of the spiders?

Hel.—Oh! they die, you know, for want of nutrition. Then I send the patient down to Brighthelmston, and a couple of dips in the salt water washes the cobwebs entirely out of the blood.—From Foote's *Devil on Two Sticks.*

Action of Salol on the Kidneys.

In a report in the *Centralblatt für Chirurgie*, October 25, 1890, it is stated that Kobert has pointed out a possible danger in the use of salol which is of importance. Salol is so constituted that it undergoes conversion into carbolic acid in the system of an animal, so that any dose is equivalent to about one-third the same quantity of carbolic acid. Hesselbach ordered for a strong girl, twenty-two years old, with acute articular rheumatism, fifteen grains of salol to be taken every two hours; but she was given by mistake double this dose, so that in eight hours she took 120 grains. This was followed by sopor, suppression of urine and death in four days.

Kola Essence Stimulant.

The *Chemist and Druggist*, November 29, 1890, gives the following formulæ for kola cordials, or what it calls "pick me ups."

℞ Tincture of kola (1 in 20) . . . 1 ounce
Essence of vanilla . . . . . 40 minims
Simple syrup . . . . . 4½ ounce
Water to . . . . . 8 "

Mix.

Dose: An ounce or more.

Roast kola nuts like coffee, grind and make into a fluid extract (1 in 2) with 25-per cent. spirit. Use this in the following:

℞ Fluid extract of kola . . . . . 10 drachms
Tincture of canella (1 in 10) . . . 1 drachm
Essence of peppermint . . . . 8 drops
Mucilage . . . . . 4 drachms
Syrup of orange . . . . . 1 ounce
Water to . . . . . 5 "

Mix.

Dose: From a dessert to a tablespoonful three or four times a day.

If the latter preparation is to be kept long it is the better for the addition of a half drachm of spirit of chloroform to each ounce.

NEWS.

—Mr. Edward Bellamy, F. R. C. S., senior surgeon of Charing-cross Hospital, London, died January 4, at the age of forty-eight years.

—A meeting was held at Elmira, N. Y., January 16, at the office of Dr. H. A. Argue for the purpose of establishing an academy of medicine.

—It is reported from Upper Sandusky, Ohio, that Dr. Neal Hardy recently amputated at the hip joint, after opening the abdomen, so that an assistant might compress the aorta.

—Dr. Jacob H. Gallinger, who was, on January 20, elected to succeed Mr. Blair as a United States Senator from New Hampshire, is 53 years old. He began life as a printer's boy, and has been by turns a printer, editor and physician.

—The State Board of Medical Examiners of Colorado met January 6, 1891. Only four candidates appeared for examination, though some thirty or forty applications were on file. Nothing outside of the usual routine business came up for consideration.

—On January 22, Prof. Sonnenburg exhibited at the Charity Hospital, Berlin, a consumptive patient who had been subjected to a surgical operation upon the chest after inoculation with Koch's lymph. The patient was said to have improved decidedly.

—It is reported under date of January 26, that a drug trust, with a proposed capital of $60,000,000, has been proposed to some wholesale drug manufacturers in Detroit, Michigan, by a promoter from New York, who represents capitalists in New York and London.

—A "Central Throat Hospital and Polyclinic Dispensary" has been started in Brooklyn, and is apparently endeavoring to supplant the Brooklyn Throat Hospital, which has been in operation for about two years. Sharp rivalry and sharp practice seem to characterize the competition.

—At the annual meeting of the Lackawanna County, Pa., Medical Society, January 13, officers for the ensuing year were elected as follows: President, Dr. Paine; First Vice-President, Dr. Barnes; Second Vice-President, Dr. Pennypacker; Secretary and Treasurer, Dr. Ward; Censor, Dr. Gardner; Librarian, Dr. Gardner.

—The President has received a package from Minister Phelps, at Berlin, containing five vials of Koch's lymph, and he has distributed them as follows: Two vials to Surgeon-General Hamilton, of the Marine Hospital Service, Washington, and one vial each to the Polyclinic Hospital, of Chicago, the Charity Hospital, of New Orleans, and the City Hospital, of Indianapolis.

—At the annual meeting of the Camden (N. J.) Medical Society, January 8, 1891, the following officers were elected: President, H. F. Palm; Vice-President, Alexander McAllister; Secretary, Joseph H. Wills; Treasurer, George T. Robinson; Reporter, Daniel Strock; Librarian, H. F. Palm; Standing Committee, H. Genet Taylor, A. M. Mecray and E. P. Townsend.

—Judge Allison, in the Court of Common Pleas of Philadelphia, decided on January 24, that members of the medical staff of the Philadelphia Hospital are neither officers, subordinate officials nor employés of the city, and that under the rule which the Mayor and heads of departments had power to make, it is the duty of the Board of Charities and Correction to elect the hospital staff annually.

—At the annual meeting of the Montgomery County, Pa., Medical Society, held January 21, the following officers were elected for the ensuing year: President, George N. Highley, Conshohocken; Vice-Presidents, G. F. Hartman, Port Kennedy, and Mabel W. Moore, Norristown; Recording Secretary, H. H. Whitcomb; Corresponding Secretary, J. K. Weaver; Treasurer, E. W. Corson.

—Dr. William J. McClure, aged 53, died at York, January 24. He represented Adams county in the Legislature in the session of 1877–78. He was also Coroner of this county from 1867–70, and held other offices prior to his removal to York, in 1880, to practice medicine. He was a graduate of the Baltimore City College and a member of the York County Medical Society. He was a native of Madison county, Indiana.

—William Faulk, living at Laurel Station, Pa., killed his wife in a fit of religious frenzy on January 23. The next day a warrant was issued for the arrest of George Knauff as an accessory before the act. Faulk declares his religious insanity was inspired by the hypnotic influence of Knauff, who claimed to be another Messiah, and ordered him to kill his wife. This Faulk did, and officers are now hunting Knauff, who has disappeared.

—The newspapers have been stirred up by the assertion that on January 18, one hundred and thirty-two Knights Templar contributed pieces of their skin to surgeons, who transferred them to a fellow-member, who had had a cancer removed from his thigh. Enough skin was secured to cover one hundred and forty-four square inches of surface. The operation took place in the Emergency Hospital, in Chicago, and it was said that the result would not be known for ten days.

—The death of Henry M. Martin, Surgeon in the United States Navy, was announced January 19, 1891. He was born in Philadelphia. He was appointed Assistant Surgeon in the navy May 21, 1870, and was promoted to Passed Assistant Surgeon on June 8, 1874. He was with the Alert, on the Asiatic Station, from 1875 to 1878, and was promoted Surgeon on April 24, 1884. He was attached to the receiving ship, St. Louis, at League Island, from 1886 to 1888, and afterwards to the Swatara, on the Asiatic Station. He was retired in November last on account of ill health.

OBITUARY.

ROBERT A. TAYLOR.

Dr. Robt. A. Taylor, a promising young physician of Duluth, died December 21, 1890, age 31, of typhoid fever. Dr. Taylor was a graduate of the Jefferson Medical College, Class 1886. He served one year at Blockley Almshouse as resident physician. Dr. Taylor was gathering about him a very large practice. Surgery was his special forte. He leaves a wife and one child to mourn his loss. His remains were brought on to this city for interment.

"This is an Age of Apollinaris Water."
—Walter Besant.

Apollinaris

"THE QUEEN OF TABLE WATERS."

"Familiar in millions of mouths as any household word.

"The popularity of Apollinaris Water is chiefly due to its irreproachable character.

"More wholesome than any aerated water which art can supply."—THE TIMES, LONDON.

"Of late years the Queen, by the advice of Sir William Jenner, has usually taken Apollinaris Water.—THE WORLD, LONDON.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York.

Sole Agents for the above Preparations.

Constipation.

Pavarn Pills are prepared especially for the treatment of Constipation. They are tasteless, harmless, and *produce natural movements of the bowels, without pain, nausea, or any inconvenience whatever.*

Physicians are requested to test these pills in those cases which they think to be incurable, also, in cases of **constipation during pregnancy.** Thousands of physicians now use and prescribe them.

Physicians will see by the **formula** (on the outside label) that each medicinal ingredient is **absolutely harmless.**

Prices: small bottle, (25 pills), 25 cents; large, (150 pills), $1.00. Liberal discount to physicians.

A large bottle will be mailed to **any physician,** for trial, on receipt of 25 cents in postage stamps.

Prepared by C. L. TOPLIFF, New York. Depot, 115 Fulton Street.

Suppositories

FOR THE TREATMENT OF

Hæmorrhoids or Piles.

Topliff's Suppositories supply what physicians and the public have long desired, namely, a *simple, effective,* and *perfectly harmless* remedy for hæmorrhoids or piles.

Physicians thoroughly approve of these Suppositories because they are so effective, and will not interfere in the slightest degree with any other medical treatment.

Price 50 cents per box, (24 Suppositories). Liberal discount to physicians. Two boxes will be mailed to **any physician,** for trial, on receipt of 25 cents in postage stamps.

Prepared by C. L. TOPLIFF, New York. Depot, 115 Fulton Street.

FRAUD.

Unscrupulous parties are selling an inferior Wine, calling it Royal Tokay, thus profiting by the numberless Medical Editorials written about our genuine product. The Wine cannot be used as a substitute for ours, and many physicians have unjustly blamed us for damage done, imagining they were securing our Wine, which they had already tested with complete satisfaction. Your patients will not secure the Wine you prescribe unless you specify CALVICO TOKAY, by which name it will hereafter be known.

A CASE WITH A LESSON IN IT.

We have frequently referred to the necessity of keeping the pregnant woman supplied with those chemical substances which she must give to the child in the formation of its little frame, and the dire effects which may result from a deficiency of those substances. The headaches, neuralgias, spinal tenderness, and some of the many disorders of digestion, and even mental failure, may be all prevented or relieved by supplying to the mother the chemical food her system demands.

We have noticed a few cases where the most serious results have occurred to the mother by such a deficiency, one of which is well worth relating. Mrs. M., aged 30, pregnant with her third child, suffered from the second to the fifth month of her pregnant term with gradually failing strength and health, and nervous irritability. She was very restless nights for three or four days, the peculiar restlessness of complete nervous exhaustion, and was irrational for more than a week.

At this time I advised that she have a teaspoonful of Murdock's Liquid Food every hour in milk, and a little wine every four hours. The third night she had fifteen drops of hydrobromic acid dil. every three or four hours, which was continued for a week. The liquid food after a week every two hours, and all other medicines were discontinued. Her bowels were moved with a mild laxative at first, and afterward became regular. Her tongue cleaned quickly and her skin assumed a more natural appearance.

At this writing, less than three weeks from our first visit, the patient is able to sit up an hour at a time, is quite rational and cheerful, has a good appetite, the bowels are quite regular, there is no headache, and but little spinal tenderness. She sleeps reasonably well if fed frequently. She is allowed to suit her taste in her diet. The child is quite active, and the mother is progressing so nicely that it is hoped that she will pass safely through her confinement, which is nearly at hand. She will be kept on the liquid food and the phosphates until her confinement after which, the condition will suggest the treatment. This is the most marked case of a starved nervous system we have ever seen, and the benefit derived from the treatment proves the theory as to the cause of the trouble.

Apropos with the above, comes the question of the selection of nutritious foods for those many cases which demand strong and immediate nourishment. The food used in the above case has produced marvelous results for us in some of those extreme cases in which we have used it.

In one case of nervous exhaustion the insomnia was absolutely painful. When the exhaustion forced the patient to sleep there was an immediate sense of falling or approaching death, or there were hallucinations which were appalling, rendering the nights unbearable. One teaspoonful of Murdock's Liquid Food so nourished the system the first night it was given that the patient sank into a quiet, refreshing sleep which lasted, with a single awakening, until morning, and the improvement the patient obtained was most striking.

One case of mitral regurgitation with leucocythemia and nervous exhaustion improved more rapidly on this food than on all other measures combined. In cases of nervous exhaustion and brain tire, its effects are most marked, as we have experienced many times in the past five years in the frequent personal use of the agent. It contains the principles of pure, healthy blood and nerve tissue ready for immediate assimilation. Fourteen per cent. of the entire quantity is uncoagulated albumen, as we have demonstrated by actual analysis.

We have tided babies over critical periods often with a few drops in its usual diet. We have given it to dipsomaniacs with or without non-alcoholic stimulants with superb results. The sole objection our patients have to it is its odor. Its taste is not disagreeable; it has the odor and appearance of blood. All objections are soon forgotten, however, in the results of its action upon the nutrition of the system, and the patient soon learns to like it, and often craves for it, drinking it from the bottle or a glass readily, like any beverage. It ought to be the food par-excellence for rapid appropriation in all conditions of exhaustion.

P. S.—Phosphates act well with the Liquid Food.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{30}$ gr.), Atropiæ Sulph. ($\frac{1}{500}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{50}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

Clinical Lecture.

APPARENT HEMIPLEGIA FOLLOWING THE GRIPPE.—ACUTE CATARRHAL JAUNDICE.

BY MORRIS LONGSTRETH, M. D.,

PHYSICIAN TO THE PENNSYLVANIA HOSPITAL.—LECTURER ON PATHOLOGY, JEFFERSON MEDICAL COLLEGE.

Gentlemen: The case before us, which was sent as one of hemiplegia due to the *Grippe*, will serve as an illustration for a talk on the many effects produced by the epidemic influenza of last winter. This woman presents the following history: She is forty-seven years old, single, and has been nine years in this country. By trade she is a dressmaker. She comes to us with the history of a partial loss of power in the right arm and leg; not that she is unable to move these members, but she cannot walk nor use her limbs with any precision or skill; in fact, she cannot do any of the useful things essential in daily life and work. She has no family history which bears upon her case. Personally she has always been healthy. There is an indefinite history of enlarged glands some time ago; but she states that she has not seen a doctor for eighteen years. In common with many of the rest of us, she had an attack of influenza last Christmas, and has not been well since. Her present trouble dates from four months ago. It began in a curious way for hemiplegia—at least of a centric origin. She experienced a feeling of malaise, of being out of sorts; a pain appeared in her right hip, not connected in any way with the abdominal cavity. We can scarcely call it a pain; it is rather a twisting sensation, unusual in character and indefinite in nature. This feeling spread up and down in her body, and took away the power of movement. There was a sensation of loss of power, which lasted only for a little while. After experiencing tingling in the fingers, the loss of power became less apparent, lasting on an average for twenty minutes, and coming and going. There were no head symptoms, and the eyesight was good. Ever since her experience with the influenza, her digestion has been impaired, her appetite and bowels were upset, and a general indefinite run-down condition of health has settled upon her. There has been at no time any evidence of the loss of power in head or face. On protuding her tongue, we can see that she holds it straight out. The tongue is covered irregularly with patches and her breath is heavy. Her heart and lungs are normal, and nothing exists in the abdomen abnormal that we can detect. Flocculi of mucus are found in the urine, with a slight trace of albumin, mucous corpuscles, imperfectly formed epithelial cells, and bodies which approximate in their appearance hyaline casts. Probably the mucus had collected in strings, giving this simulation of hyaline casts. Crystalline material is abundant in the urinary secretion. This shows that the kidneys are able to separate the waste products of the blood fairly well. I believe that, when enough uric acid, urates, oxalate of lime, etc., are present, even if there is sufficient change in some parts of the kidneys to form casts, it will make but little difference in diagnosis or prognosis; for this shows that the kidneys are acting in a fairly normal manner.

The specific gravity is above 1.020, showing that there was no deficiency in solid matter excreted. The grip of each hand is not good at all, being poor in each instance. She moves her limbs quickly, however, and without hesitation. There has been no rise in temperature. Before deciding exactly what condition we have before us, let us go a little farther into the digestive symptoms. You will notice that the tongue is smoothed off, as if it had been skinned. This is diagnostic of a coating which for some reason

or another has desquamated, similarly to a blistered surface of the skin. It should be velvety and natural in appearance, or else essentially coated. A patch of coating has appeared from day to day on the tongue, creeping around. It sheds off rapidly, either from contact with the food or teeth, or because the desquamation is severe. This shows that the irritation must be severe and is even more unfavorable than that the tongue should remain heavily coated. The coated tongue is dry naturally; it becomes no moister after wetting. Apply your finger to this tongue, you will find that, after one or two touches, the surface of the tongue is dry. It is likely that this intense irritation of mucous surfaces has spread down the alimentary tract since last January, acting almost as severely as if one-half the surface of the skin were blistered. That this effect has been produced by the "grippe" is well known. Many cases have recovered perfectly. In many cases of the influenza, the respiratory mucous membrane was left in a bad condition. This effect can be seen more sharply and distinctly, and hence is more liable to be well treated and the condition corrected. But the stomach and intestines are more used to non-attention; their symptoms are not so sharply marked; the patient is able to bear up under them better. But in this woman we have a story of depression in nutrition which is a fair example.

What proof can we seek in this woman to find if her story of serious illness is true. I have been in the habit of looking at the finger nails, for this reason: that, in the various fevers and the many other conditions which depress nutrition, the hair comes out in convalescence or scales drop off the skin. In febrile processes there is a check of the natural growth of the tissues of the body. On the return of health these tissues start again to grow. If you will examine the roots of the hair in a convalescent patient, you will see that the ends of the hair are splintered and weak. In the skin this condition is not so perfectly or readily seen; but in the finger nail we find the same nature of epithelial growth. They stop growing in serious diseases, and bear their records for long periods of time. In this woman, four months after her attack, it is too late to look for the record of serious illness in her hair, but the nails of the hand bear record for many months, that of the thumb for nine months, while the great toe nail is characteristic for two years. In hemiplegia there is a stop of growth on the affected side; the nutrition is impaired just as it is in a broken arm. On looking at this woman's hand, we find a third way up on the thumb nail, half way down on the finger nail and on the little finger nail at the end, a marked depression or thinning out of the nail. Normally we have a smooth polished nail, but in these cases there is a depression and a lack of appearance of strength which is characteristic when once noted. If this were a case of hemiplegia, occurring four months ago, there would be a depression on the affected side later than that one produced by the influenza; but we find on examination that this is not so. The question presents itself, is the "grippe" a sufficient cause for the production of hemiplegia? We know what part intestinal mischief bears in the production of marked nervous trouble; we know the effect injudicious food has in children in causing convulsions, but it is hard to say what amount of disease the curious epidemic of last winter is capable of leaving in its path.

The electrical examination does not favor at all the hemiplegic view; the reflexes on the right side are somewhat exaggerated, but this I believe is due to want of proper exercise and use.

In considering the treatment of such a case as this we must remember that the tongue points to the existence of a general condition of digestive depression. The feeding is one of the most important points. In catarrh of the intestines, the treatment varies according to the intensity of the symptoms. The use of some sedative application, such as bismuth, is indicated, to relieve the irritation which exists. This is shown by the discoloration of the mucus seen in the stools, similar to the white patches found on the tongue. To restore intestinal action and secretion, minute doses of calomel can be very advantageously combined with bismuth. We have been giving this woman every three hours a one-twenty-fourth of a grain of calomel with ten grains of bismuth. The tongue may not get free, but even if it coats over, it will be a gain, as we have shown. This simple treatment is rapidly improving this woman's condition.

Acute Catarrhal Jaundice.

The next patient, a woman sixty years old, has nothing in her family or personal history which bears upon her case. She

says that she has been subject to "liver attacks," in which the chief symptoms were nausea, choking, and a band-like pressure-sensation over the epigastrium. The skin never became yellow, and she had no severe colic or pain in the abdomen. Her present attack began with a chill, a severe pain in the region of the liver, and nausea, followed shortly by fever. Almost immediately jaundice appeared, and the bowels obstinately refused to act. The temperature was 102⅖°, falling on the next day to almost normal. Night and morning it remained nearly even, but it was irregular throughout the day. Occasionally she experienced a chill. Enemas of soap and water were tried ineffectually. Subsequently relief was obtained by the addition of glycerine. Since October 1, she had no serious rise in temperature until the 24th. Since the 26th, she has been taking one or two compound colocynth pills. Her movements, which had been slate-colored before, showing no evidence whatever of bile, now became darker, and the tongue cleared up. It had been thick, yellow, swollen and dry. The conjunctivæ, which have been yellow, still remain so, due to thickening, not to staining. The face never was very yellow, the color being better seen on the abdomen. Her appetite and sleep have each improved. Her bowels move regularly, and she is gaining strength. The colocynth acts with more and more effect. She was taking three pills; she is now down to two. This will be reduced to one in a short time. The urine, which was dark in color and contained considerable bile, now shows on testing that that element has disappeared.

COMMUNICATIONS.

TREATMENT OF CARBUNCLE.

BY ARTHUR E. SPOHN., M. D.,
CORPUS CHRISTI, TEXAS.

Several years ago I was called to see a patient, living fifty miles away in the country—a very frequent occurrence in Southwestern Texas, where pastures contain from ten to five hundred thousand acres in one enclosure. I met on the road a man suffering fearfully with carbuncles. He had three: one on his face, one on his wrist and one on the back of his neck. I don't think I ever saw any person suffer as he did. The only medicine I had with me which I thought could give relief was a saturated solution of chloral hydrate in water and glycerine. Of this I poured one teaspoonful over bread poultices, and applied them to the carbuncles, expecting as soon as the man was relieved of pain to make the ordinary incisions. To my surprise he was soon relieved of pain, and the next morning the carbuncles looked so much better that I concluded to continue the treatment, without making incisions. I did not see this man again for about two months, when he came into my office for a prescription of the medicine I used, saying that he had had no more trouble after I left; that his carbuncles had diminished in size without sloughing, and that they soon got well. The carbuncle on his back was fully three inches in diameter. He has had several carbuncles since, using the same treatment successfully. I have not seen him recently; but I am told that he is falling off in weight. I did not examine his urine at the time, but think he is probably suffering with diabetes.

I have now under treatment four cases of carbuncle. It is strange that nearly all the cases of carbuncle I have seen in this climate occur during February, March and April. This fact has impressed me with the idea that they are due to some climatic condition. Two of my patients have carbuncle on the back of the neck, one on the back, one on the side of the neck. I am treating these cases with a ten per cent. solution of chloral hydrate in glycerine and water, applied constantly by means of absorbent cotton. The patients are doing well and having little or no pain. Internally I give sulphide of calcium. I have a patient who had carbuncle in April, 1887, and again in September, accompanied by numerous boils. He has diabetes, his urine containing six grains of sugar to the ounce. He now has caries of the ilium on the right side. I removed the carious part twice, but the bone would not take on healthy action. I am now irrigating the diseased surface with a ten per cent. solution of phosphoric acid. The patient seems to be improving; and there is very little discharge from the two sinuses leading down to the bone, one of which passes in the direction of the sacro-iliac articulation.

While speaking of this patient, I wish to mention an artesian well in this city, the water of which is very beneficial in cases of diabetes. The well is about 400 feet deep; flows about five feet above the surface of the ground in a small stream; and its capacity

is about 60,000 gallons daily. This water contains principally chloride of sodium and sulphate of sodium, strongly impregnated with sulphuretted hydrogen gas. It sparkles in a glass like champagne. It is laxative, in doses of an ordinary glassful; in larger quantities it is a brisk cathartic, causing little or no inconvenience. The water belongs to the city and is free to all. It will not bear transportation under the present methods of bottling.

I was very much pleased when I read the lecture on the treatment of carbuncles by Prof. Verneuil of Paris, in the REPORTER of February 11, 1888. I have used carbolic acid, but not as a spray. I think the treatment by chloral is quite as successful and more easily carried out. The principal merit in the two methods is the avoidance of the old crucial incision, which I find still recommended in my latest works on surgery. I never make incisions into a carbuncle; they are useless and painful, and expose a fresh surface to the virus. It is impossible to open every cell, as it were; and I consider the crucial incision to be a relic of surgical barbarism. There may be cases, with an accumulation of pus, requiring an incision; but they are very rare. A man came into my office some months ago, and asked me to look at the back of his neck. He was a railroad magnate, and of course, very anxious to get well. He had been told he was getting a carbuncle, and that a crucial incision was necessary. I don't know about the carbuncle, but I do know he had the incision. The skin on a man's back, is—as near as I can estimate it—about a quarter of an inch thick; in this case I think it was about three-quarters of an inch; the length of each incision was two inches, and when I looked at them I thought, if I had my choice between such an incision and a two-inch carbuncle, I would take the carbuncle. Whether the man ever got the edges of that incision together or not is questionable; but I fancy he carries a crucial brand, which in Texas is considered quite an ornament.

—The first patient in this country to receive the lymph inoculation, died, in New Haven, Conn., Feb. 2, and another lymph patient, who has been under treatment for nearly two months, was then at the point of death. The first named was a man but little over thirty years of age and was not in an advanced stage of consumption when he began receiving treatment.

RESECTION OF THE OPTIC NERVE.

BY L. WEBSTER FOX, M. D.,
PHILADELPHIA.

The loss of an eye under any circumstances or conditions is a very serious affliction. The vacant stare and dull look of an artificial eye can never compensate, for one which may be disfigured by a leucoma or partial atrophy, for even such eyes are preferable to wearing glass ones, be they ever so well matched. No matter how smooth an artificial eye is polished, sooner or later the secretions corrode its surface and those irregular projections cause more irritation, and the result is more offensive secretions, which become dry and harden upon the surface of the eye, usually appearing as a horizontal band over the cornea. To morbid individuals, especially women, these results are, to say the least, disagreeable, and to the observer equally so.

The question has often arisen: How can we best overcome the necessity for an enucleation. Eyeballs are removed, as a rule, for three indications:

1. If wounded or cut in the ciliary region (the danger zone), to prevent sympathetic ophthalmia.

2. If atrophied, to make room for an artificial eye.

3. For new growths (tumors).

The first indication is the most important. If we can prevent sympathetic ophthalmia we also may save an eyeball; but by saving the eyeball we do not necessarily prevent sympathetic ophthalmia. In the second case an atrophied eyeball is disfiguring and is removed for cosmetic purposes, and because it may be a hiding place for new bone development, which may remotely produce sympathetic irritation. I have frequently removed a stump and found bone shells with edges as sharp as a splinter of glass. With such a foreign body irritating it, an optic nerve might readily be the focus of migratory ophthalmia.

Where a tumor exists we have but one recourse—enucleation.

At the October meeting of the *Société D' Ophtalmologie*,[1] of Paris, the question of resection or laceration of the optic nerve was discussed, especially by Drs. De Wecker, Chauvel, Gillet de Grandmont and others. Dr. De Wecker, who has had exceptional

[1] *Recueil D' Ophtalmologie*, October, 1890.

facilities for putting into practice the text of his teachings, made the following remarks.

"I propose to continue the campaign I have undertaken against the abuse of enucleation, and I firmly believe that by making more popular the simple resection of the optic nerve in cases where we have danger of migratory ophthalmia, no more eyes will be taken out, except when they are the seat of a neoplasm (tumors).

"If the transmission of migratory ophthalmia by the optic nerve is confirmed (and I am convinced of it), the simple resection of the nerve will afford a sure means of preventing it. Boucheron and Schoeler's method, which includes cutting the ciliary nerves, does not, however, answer the purpose. The only way to prove conclusively that resection of the optic nerve can take the place of enucleation is that a large number of resections shall be made and the results noted. The operation must also be made as simple as the operation for enucleation. If we were to follow the complicated operations as described by Schweigger or Pagenstecher it would certainly never become popular.

"Being aware of the difficulties which beset one, and fearing that in the midst of operation, by an unlucky cut of the scissors, a hemorrhage should follow, it occurred to me to forego the section of the nerve, which is the most difficult part of the operation, and simply to tear off the nerve near its optic entrance. This idea was suggested to me by the cases recorded, in which the eyes were torn out with the optic nerve attached, and also the savage custom of the Tyrolese wrestlers, who put eyes out by introducing their thumbs into the orbits on the temple side. I suppose that such displacement of the globe could only be effected after tearing off the nerve at its optic attachment. On a recent visit to the Tyrol, a wrestler presented himself with his eyeball hanging on his cheek and asked whether the eye could be replaced and be useful to him. Being answered in the negative, he seized the eyeball, tore it off and flung it to the ground. My experiments upon the cadaver were made with a view to ascertain whether or not a nerve could be torn. With my double hook I have never been able to tear off the nerve at its entrance into the orbit, even when pulling with all my strength. All I could do was to sever the nerve by pulling with the hook; in other words, the hook cut its way through the nerve. On several occasions I succeeded in tearing the eyeball from the nerve, the vitreous humor escaping through the opening made by the head of the nerve disappearing. I also tried to tear the nerve off as it entered the orbital foramen; but I signally failed in this also. We have a well-known case, in which a drunken man fell against a door, the key of which was projecting, and the eye thrust itself through the ring of the key, the nerve being completely severed. In another case, a horn of a cow drove the eye into the maxillary sinus. Here also the nerve was severed. In these instances the traction did not act directly and exclusively on the optic nerve, as in my experiments on the dead body. In the case of the intoxicated man who thrust his eye through the ring of the key, all the weight of his body exerted a traction on the whole funnel-shaped bundle of muscles of the eyeball. The traction pressed on their insertions around the passage of the optic nerve into the orbit, and tore them off from their insertion simultaneously with the sheath—to which they are attached. This is also the reason why we do not find the tearing off of the nerve isolated; the internal rectus being always detached in this sort of traumatism. We must therefore give up the combined operation of resection and tearing, in place of the simple resection. All that is left for us to do is to try to improve the operation of simple resection; to make it always feasible and easy so as to supplant the repulsive enucleation."

M. Chauvel who made some experiments upon the elongation of the optic nerve stated that he was never able to tear the nerve of the human eye, although he was able to do so in rabbits.

M. Gillet de Grandmont corroborated Dr. De Wecker's statements, especially those relating to tearing the globe from the nerve, and related an instance in which a woman in a fit of melancholy, suddenly thrust her index finger and thumb into her orbit. Her strength was so great that with her left hand she took hold of the eyeball, tore it off with three centimeters of the optic nerve, and threw it on an adjacent bed. This was the work of a few seconds. She made a similar attempt on the right eye, but the attendant seized her right hand, only, however, after the patient had succeeded in thrusting her index finger under the inferior muscles and had torn them from the globe. A severe hemorrhage followed, no other complications arose,

and in a few days she recovered the sight in her right eye.

We miss very much in the foregoing remarks a description of the exact way in which De Wecker, Grandmont and others perform resection of the nerve.

A few years ago Mr. Brudnell Carter and Dr. T. Herbert Bickerton performed an operation for opening the sheath of the optic nerve in optic neuritis. Mr. Carter designed special instruments for this operation, and the difficulties were made easy for exposing the optic nerve. In performing this operation, I found but little difficulty in following Carter's method. The one obstacle was, that the orbital fat would constantly get in the way. Dr. Shakespeare, who assisted at this operation, suggested a speculum shaped like Sims's uterine speculum. With this instrument the difficulties were overcome in a subsequent operation.

If resection of the optic nerve can be performed with complete protection against sympathetic ophthalmia, it will be a boon to many unfortunates. The wearing of an artificial eye is as annoying as it is unsightly.

The details of the operation for resection are essentially as follows. The lids are separated with the ordinary ophthalmostat; a vertical incision is made through the conjunctiva over the insertion of the external rectus muscle; the conjunctiva is dissected off as far back as the external canthus will permit. This exposes completely the muscle. Two silk threads are then passed through the muscle near its tendinous insertion. These threads will be required in a subsequent stage of the operation, to unite the detached muscle to the eyeball. The muscle is then cut and drawn to the temple side. This exposes the globe. With curved scissors, all tissue is then separated from the eyeball. The optic nerve is found by passing a hook—which is nothing more than a strabismus hook bent at a right angle. This hook brings forward the nerve, and then the retractor is passed downwards until it meets the nerve, and is then passed down and out, keeping the adipose tissue out of the way. A second bent hook is inserted under the optic nerve, and also pressed backward. A certain portion of the nerve becomes exposed, and with a delicate flat forceps the nerve is grasped and held firmly. This is to prevent hemorrhage from the ophthalmic vein and artery (central) after the cut with the scissors. The eyeball is rotated forward, so that the non-severed nerve becomes exposed and a small piece of its bulbar end is cut off. By keeping pressure on the orbital end of the nerve for a few minutes, all danger of hemorrhage is aborted. The eyeball is then rotated into place, and the external muscle is re-adjusted. Over this the conjunctiva is replaced, and it is held in position with black silk, which may be removed in three days. Antiphlogistic dressings are applied day and night for several days. Very little reaction follows, and in a week or ten days the eye has assumed its normal appearance, with no disfigurement, and the action of the muscle is complete.

CASE OF ULCERATIVE ENDOCARDITIS.

BY C. A. VEASEY, M. D.,
RESIDENT PHYSICIAN OF THE JEFFERSON MEDICAL COLLEGE HOSPITAL, PHILADELPHIA.

The subject of this account was a woman, twenty-five years old and married, who was admitted to the Jefferson Medical College Hospital, under the care of Dr. F. P. Henry, Visiting Physician, on June 25, 1890. Three weeks before, she had been very much frightened during a fire in the neighborhood of her home, and at the time she suffered a great deal with palpitation of the heart, which was soon followed by paroxysms of præcordial oppression and pains of great intensity shooting into the left axilla and down the left arm, with dyspnœa of the most painful character. During the paroxysms her face became cyanosed, and she expected every moment to be her last, her facies indicating great anxiety and terror. After admission to the Hospital she had paroxysms similar to those described by her friends. Sometimes there would be no paroxysm for three or four days; then she would have a most violent one, lasting for an hour or more before relief could be given, and being followed by a number of lighter attacks. On some days there were as many as eight in the twenty-four hours.

When first admitted to the Hospital the woman was able to walk around the ward; but after July 1, she was confined to her bed. During the greater part of the time she was compelled to use a bed-rest, and to remain in a half-sitting posture, on account of the great dyspnœa with which she suffered. She had a severe cough with, at first,

scanty expectoration, soon this was superseded by a profuse muco-purulent expectoration, frequently streaked with blood. She also complained quite often of chilly sensations, so that external warmth was used almost constantly. Her finger-nails were blue, her tongue red and swollen and marked with indentations by the teeth. A few days after her admission there was developed severe and excruciating pain in the region of the right kidney, and the abdomen was quite tender to the touch. There was also much pain in the region of the right nipple; but it was little compared with that on the other side. The patient's appetite was very poor; in fact, she could take nothing but some liquid diet, and towards the end of her life a small quantity of stimulus.

The woman said that she was six months pregnant; but her pulse was always so rapid that the fetal heart sounds could not be distinguished with absolute certainty.

Physical examination of the heart revealed a loud mitral systolic murmur, transmitted to the axilla and to the angle of the scapula. The murmur was so marked that it seemed to take the place of the first sound of the heart. The second sound was changeable, being sometimes pronounced and at other times feeble. The area of cardiac dulness was increased in both directions. The impulse was diffused, and the pulse was feeble, irregular and rapid, ranging from a hundred and twenty to a hundred and sixty beats per minute. Over the lungs percussion dulness was found in spots. Respiration was feeble and rapid—usually thirty to fifty per minute—and râles were heard in various parts of the lungs. No pulse could be detected in the right arm at any point. The urine was scanty, of a yellowish-red color, acid, with a specific gravity of 1.030, on boiling it deposited albumin to about half its bulk; it contained no sugar, and a few pus-cells and some hyaline casts were found on microscopical examination.

The temperature record was quite peculiar. At the time of the patient's admission to the Hospital the temperature was 100° F.; the next evening it was 101°; the next morning it was 100°. That evening it was 102°; and there was a slight fall by the following morning. On the evening of the next day it was 103.4°, it fell the next morning to 98.1°, and rose again in the afternoon to 102.2°. The temperature was of this irregular character for two weeks, making wide variations, after which, up to the time of death, which was July 15, it varied from normal only about one degree.

The diagnosis of the case was: ulcerative endocarditis and miliary tubercle. It was also thought that the absence of pulsation in the right arm was due to the presence of a thrombus in the subclavian artery, but it was supposed that this was so covered by the clavicle that no tumor could be either felt or seen.

At the autopsy, the pleural sac was found to be adherent to the chest-wall on both sides. The lungs were filled with miliary tubercles, and infarcts were found at different points, some of which had caused rupture of the vessels, the adjoining lung tissue having become œdematous and soft.

The heart was largely hypertrophied, the left side was firmly contracted, while the right contained a clot. Upon opening the heart both ante-mortem and post-mortem clots were found on the right side, and a large ante-mortem clot was found at the aortic valve. One leaflet of the mitral valve was entirely absent, and there were vegetations on the side from which the leaflet was absent which covered at least as much space as a dime would cover. These vegetations were about a quarter of an inch deep and had ulcerated.

In the abdominal cavity all the organs were congested. There had been peritonitis with adhesion on the right side; the liver and kidneys were full of miliary tubercle and infarcts—only about one-half of the left kidney and one-fourth of the right being in a state to excrete urine. The spleen was enlarged, softened and full of miliary tubercle. No tubercles were found in the intestine. The uterus contained a fetus about seven months old. [It was desired to make an attempt to save the child by an operation just before the death of the mother, but the friends of the patient objected.] Confirming the diagnosis of obstruction to the lumen of the right subclavian artery, at its middle third, an aneurism was found which had been spontaneously cured by the formation of a clot which was supposed to have been deposited upon some material carried into the circulation from the seat of the vegetations.

The chief points of interest in this case, which is a typical one of acute ulcerative endocarditis, are: first, the shock of fright which brought to light symptoms of heart disease, which had before been latent; sec-

ond, the marked symptoms referable to the right kidney, which during life were attributed to emboli—a diagnosis corroborated post-mortem; finally, the healed aneurism of the right subclavian artery. The question whether the consolidation of the aneurism was due to coagulation having for its point of departure emboli derived from the diseased heart, was one which could not be determined. It is, however, one of considerable interest.

The case, although an isolated one, is of interest if only as demonstrating the well-marked features of an affection which, not many years ago, generally passed unrecognized.

MINOR UTERINE SURGERY.[1]

BY CHARLES P. NOBLE, M. D.,

SURGEON TO THE KENSINGTON HOSPITAL FOR WOMEN, PHILADELPHIA.

For several years the attention of gynecologists has been so largely occupied with abdominal surgery, and particularly with the diseases of the Fallopian tubes, that but little has been said concerning the diseases peculiar to the uterus. It may be supposed by some that the reason so little has been heard of the uterus and its diseases is that the labors of the past have placed our knowledge of these subjects upon an enduring basis. I am satisfied, however, that the true reason has been indicated above, and am the more convinced of it by the recent appearance of a paper absolutely denying the truth of the teachings of the past, concerning, more especially, the treatment of diseases of the uterus, and attributing evils to the measures employed greater than the good they have been designed to accomplish. In view of the immense strides which have been made in our appreciation of the diseases of women, especially those of an inflammatory character, in the last ten years, and of the very different light in which diseases of the uterus now appear as contrasted with former years, it has seemed to me that it will be profitable to review the subject at this time. The ground to be covered is so considerable that I shall present my views concisely and of necessity somewhat dogmatically, so as not to consume your time unduly. Presented in this way, I hope the subject will elicit full discussion, as I consider it one of the most important and suggestive in gynecology.

Before treating of the individual diseases of the uterus requiring surgery, it will be well to consider the diseases of the uterus as a whole. It cannot be too strongly insisted upon that a very sharp distinction should be made between diseases of the uterus themselves and diseases of the uterus complicating, or complicated by, diseases of the uterine appendages. This is the key to the situation, and upon a right appreciation of this fact depends success, or failure, or even disaster, in the management of this class of cases. Uncomplicated diseases of the uterus, barring neoplasms, seldom or never threaten life, and belong to the minor ailments of women. Where the uterine malady is complicated by inflammation of the uterine appendages, the conditions are essentially different. The disease of the appendages overshadows the disease of the uterus, which must be nearly or quite disregarded. For were it possible to cure the uterine malady without modifying the disease of the ovaries or Fallopian tubes, little would be accomplished, as the more serious disease would remain. But this is not all, for experience has amply shown that to tamper with the uterus, particularly by operation or by intra-uterine applications, in the presence of complicating tubo-ovarian inflammation, is a most dangerous thing, liable to set up acute pelvic or general peritonitis. Hence it should be laid down as a rule that operation upon or manipulation of the uterus is contra-indicated in all cases in which tubo-ovarian inflammation exists. The contra-indication becomes the more absolute the greater the gravity of the complicating disease of the appendages.

The experience of the past has shown the truth of the foregoing statements, and the knowledge of the present concerning the nature of pelvic inflammation has rendered the whole subject easy of comprehension. Formerly, various explanations were offered, some of them quite fantastic, as to the occurrence of pelvic inflammation following manipulation of or operation upon the uterus when "fixed," or in the presence of "cellulitis," or of "thickening." Now we know it is due to the rupture of intra-peritoneal adhesions and the escape of septic material from the diseased appendages.

The Uterine Sound.—I have but little to say in commendation of the uterine sound. Un-

[1] Reprinted from report of a meeting of the Philadelphia Obstetrical Society, December 4, 1890, in the *Annals of Gynecology*, January, 1891.

questionably, it does far more harm than good as used to-day. I believe that its field of usefulness is very limited. For the purposes for which the sound is ordinarily used, it is an unnecessary instrument. Bimanual examination teaches the size, shape, position and mobility of the uterus far more accurately than the sound, and without injury to the patient. The text-books say that the use of the sound should be preceded by bimanual examination to determine the above questions and the presence or absence of pelvic inflammation. If this be so, and the facts be determined, what is to be gained by the use of the sound? More or less uterine colic, and perhaps an acute salpingitis, when a dirty sound has been passed into a healthy uterus, or a clean sound passed with some force into a uterus in the presence of tubal inflammation. Unquestionably, the use of the sound has no place in the determination of the foregoing facts concerning the uterus. Likewise, I would condemn the use of the sound as a uterine respositor. Mobile uteri can be reposited by Schultze's method, and fixed uteri should be let alone. The sound is useful in determining the patency of the uterine canal when this is in doubt; and may be useful in the differential diagnosis of obscure morbid conditions in the pelvis, but I am convinced that the facts apparently determined by its use are often illusory, and that the practitioner who least relies upon it will make fewest mistakes in diagnosis. The sound may be used to determine the presence of fungosities within the uterus; but the history of uterine hemorrhages and leucorrhœa, with the absence of disease outside the uterus, makes the diagnosis so certain as to obviate the necessity for its use. The diagnosis and cure can be made with the curette.

Intra-uterine Medication.—I feel convinced that intra-uterine medication has been much abused, and that the cases are extremely rare which require or are benefited by the application of a medicament within the internal *os uteri*. Intra-uterine applications have been recommended for chronic endometritis and chronic metritis. When uterine leucorrhœa established the diagnosis of endometritis, and the same, with enlargement and tenderness of the uterus, not due to subinvolution or neoplasms, established the diagnosis of chronic metritis, these diseases were said to be very common—indeed, the most frequent diseases of women. Hence intra-uterine medication became a routine practice. If I am to judge from my own experience, uncomplicated chronic endometritis and metritis are not frequently met with. As an illustration, by going over a hundred cases in my case book and selecting uncomplicated cases, I find seven. If the cases of laceration of the cervix, with erosion, etc., were added, the list would be considerably increased. But in by far the largest number of cases these morbid conditions exist in relation with the inflammatory affections of the uterine appendages, preceding and causing the tubo-ovarian disease, and later being kept up by it.

In the presence of tubo-ovarian inflammation it is now generally accepted that intra-uterine applications should not be made. They can do no good, and may do great harm. Fungoid endometritis, and septic endometritis following incomplete abortion, require the curette. Excluding the foregoing, and cases of endometritis and metritis complicating laceration of the cervix, few cases remain for inter-uterine medication. And I am far from convinced that this small class cannot be more efficiently treated and more quickly cured by the dilatation of the cervix under anæsthesia with thorough curetting of the uterine canal with the sharp curette. During the past year I have thought it advisable to make applications to the whole uterine canal in three cases. One, a case of chronic endometritis in a virgin, was cured. The second, also a case of chronic endometritis in a woman the victim of syphilis years before, was improved by intra-uterine medication, and was cured when mercury and iodide of potassium were given by the mouth, in addition. The third, a case of small fibroid tumor, with menorrhagia, was made distinctly worse.

Looking back over my past results, I feel less and less inclined to make intra-uterine applications. Formerly I made applications of Churchill's tincture of iodine, and solutions of nitrate of silver to the endometrium almost daily. Before I appreciated the dangers of the practice and its contra-indications salpingitis and peritonitis were "lighted up" in a number of cases. Fortunately no deaths resulted. Since I have abandoned the routine use of intra-uterine medication in diseases of the pelvic organs accompanied by uterine leucorrhœa, my patients have been far happier (as uterine colic is only a memory), and I am satisfied that the influence of treatment has been more favorable than in former years.

Dilatation of the Cervix.—Dilatation of the cervix is advised for the cure of obstructive dysmenorrhœa and sterility due to flexions of the uterus (usually so-called congenital anteflexion), or to stenosis of the cervical canal, congenital or acquired; also as a step in the removal of polypi, small fibroid tumors and the retained products of pregnancy, and as a preliminary to the use of the curette. In selected cases I am heartily in accord with this advice. It is not possible to discuss these questions now; but the important thing is that cases of uterine disease are to be selected for dilatation, and not cases of tubo-ovarian inflammation. In such cases, when done with full antiseptic precautions, under anæsthesia, dilatation of the uterus is practically without danger, immediate or remote, and has given very satisfactory results in my hands.

The mistake of regarding cases of so-called acquired anteflexion, due to peritoneal adhesions or shortening of the utero-sacral ligaments, as cases of uterine disease is particularly to be guarded against. The folly of expecting to benefit inflammation of the peritoneum or of the uterine appendages by dilating the cervix is apparent; and I am convinced that all the disasters following dilation of the cervix are to be attributed either to this error in practice or to poor antisepsis.

Rapid dilatation with the steel dilators has always been employed, the pattern of Goodell having been commonly used. I have never seen a tent introduced into the cervical canal; nor have I seen the hard rubber dilator used.

The Curette.—The uterine curette is a most valuable instrument, and is indispensable in the treatment of uterine fungosities and for the removal of the endometrium in certain cases of menorrhagia. I believe it capable of rendering good service in the treatment of certain cases of congestive and obstructive dysmenorrhœa—in which the seat of pain is in the uterus, and the cause, morbid processes taking place therein—by removing the endometrium, particularly near the internal os. After incomplete miscarriages, and in septic puerperal endometritis, the curette is useful to remove necrotic tissue; but in these cases its use should be preceded by the finger, used as a curette, by which alone can the state of the uterine cavity be determined. In such cases the finger is the best curette. In all cases I precede the curetting with dilatation of the cervix, and follow it with the intra-uterine douche and intra-uterine iodoform gauze packing, which acts as a capillary drain.

In cases of chronic endometritis without complication dilatation and curetting will either effect a cure or greatly facilitate subsequent intra-uterine medication.

In curetting full antisepsis should be maintained, and the same care be used to select uncomplicated uterine cases. Anæsthesia is essential to thoroughness. The curettes of Martin and Schroeder have been used. The dull curette should be regarded more as an instrument of diagnosis. It is useful in cleaning the uterine cavity of débris before using the douche. It also finds a place in puerperal septic endometritis.

Laceration of the Cervix.—Probably no subject in gynecology has excited more discussion than that of the pathological importance and the treatment of laceration of the cervix. I am in accord with those who regard laceration of the cervix as a lesion of importance in the causation of pelvic disease, and the operation devised by Emmet for its repair as a useful addition to surgery. Certainly many lacerations of the cervix, occurring during labor, heal spontaneously during the lying-in, and are of no practical consequence to the puerpera; others heal more or less perfectly, and involution of the uterus taking place fully, no ill consequences follow. But the history of laceration of the cervix in many cases is very different. The laceration does not heal, the cervix gapes open, involution of the pelvic organs does not take place, pelvic congestion is kept up and uterine catarrh and menorrhagia follow. The general health is more or less affected, depending upon the vigor of the particular constitution, and the duration of the local disease. In some cases extensive reflexes are developed; but the conservative man will ever bear in mind the possibility of overlooking neurasthenia and hysteria in this class of cases.

Local and general treatment will effect a cure in many of these cases without operation. Rest, tonics, regulation of the bowels, ergot, hot water, vaginal douches, the application of glycerine tampons, painting the cervix with Churchill's tincture of iodine, together with scarification of the cervix, will frequently improve the condition so markedly as to effect, practically, a cure. But often this treatment proves ineffectual and operation is necessary. Another indication

for trachelorraphy is the existence of laceration of the cervix as a complication of retroversion or retroflexion of the uterus. Not infrequently the malposition cannot be corrected until the intra-vaginal cervix is restored by operation. It is important that endometritis, existing as a consequence or as a complication, should be cured before closing the laceration. Where this is difficult or impossible, and in all cases in which uterine hemorrhage is a feature, the trachelorraphy should be preceded by dilatation of the cervix and curetting of the uterus. Trachelorraphy done under these conditions has given very satisfactory results in my hands. When done for supposed reflex effects, due to cicatricial tissue, the outlook is not so promising.

It will be observed that the operation has been recommended only for uterine disease. When the uterine diseases exist in connection with inflammatory disease of the appendages the operation is contra-indicated. Under these circumstances, there is great danger of causing acute peritonitis; or this failing, drainage from the uterus is interfered with, and subsequent acute attacks of salpingitis promoted. In a neglect of this contra-indication lie most of the dangers and disappointments of trachelorraphy.

The relation of laceration of the cervix to tubal disease is a subject worthy of careful study. The laceration of the cervix is a frequent cause of subinvolution of the uterus and endometritis is generally believed. That endometritis causes salpingitis by extension is also true. Hence it appears probable that laceration of the cervix sustains an important relation to salpingitis as one of its predisposing causes. The relation between laceration of the cervix and cancer also is probably more than accidental. These considerations are further inducements to repair all lacerations of the cervix which are causing active symptoms.

I believe that trachelorraphy, done under the conditions laid down, is a perfectly safe, and very valuable, operation; and that the present tendency to decry its usefulness arises from a failure to observe its proper indications; or to carry out the principles laid down by its inventor for the operation itself. Of lateral and posterior incision of the cervix I shall say but little. I believe that the field of usefulness of these operations is limited, but that, in exceptional cases, they may be valuable.

I hope I have made it clear that my own experience has made me a firm believer in the value of minor uterine surgery for uterine disease. It seems equally clear to me that the cause of disappointment in the past, when it has been met, has been a failure to properly study the cases; and thus uterine surgery has been employed for other than uterine disease. Also that the disasters of uterine surgery have been due to inefficient antisepsis, or to the fact that operation has been done in the presence of disease of the uterine appendages, more especially pyosalpinx and abscess of the ovary.

When it was believed that inflammation of the appendages was cellulitis, which was caused by, and kept up by, disease of the uterus, and only to be cured by curing the uterine malady, it was perfectly logical to attack the uterus with our therapeutic resources. But experience has shown the dangers as well as the futility of this method, and modern pathology has brushed away the apparently rational basis upon which it rested. It is upon this ground that I have opposed useless and dangerous uterine treatment in complicated cases of pelvic disease.

Society Reports.

PHILADELPHIA OBSTETRICAL SOCIETY.

Meeting, December 4, 1890.

After hearing Dr. Noble's paper on

Minor Uterine Surgery

(see p. 156),

Dr. Joseph Price said: I wish in the first place to thank Dr. Noble for the fortification of my paper which he has given in the first half of his paper. The last half of his paper seems in large measure a contradiction of the first. A short time ago, before the County Medical Society, I had the pleasure of calling the attention of the profession to the great mischief done by minor gynecological tinkering. Dr. Noble starts out by talking about the diseases of the uterus and the minor ailments of women. I want to repeat that none of us in our own homes consider any disease of the uterus as a minor ailment, or any deviation from health as a minor trouble. Again, in speaking of methods of treatment, he alludes to applications in the presence of cellulitis, that myth which has long since been brushed

away. Again, he alludes to fixed uteri and recommends that they be let alone. A fixed uterus rarely means simple uterine disease. As a rule it means a great deal more, but not many of us are willing to let fixed uteri alone and the patient suffering with the complications incident to this fixation with extensive tubal and ovarian disease. For instance, here is a pus tube six inches long which contained half a pint of pus removed from a case with fixed uterus. On the opposite side was an abscess of the ovary containing half a pint of pus. These are common conditions. Dr. Noble states that early in his experience he had three cases of salpingitis following tinkering. with one death. Many of these cases have resulted from the uterine medication and traumatism which a few years ago was so common. Dr. Engleman has recently read a paper of 154 or 158 pages before the American Gynecological Society on the hystero-neuroses, on which he dwells at length, and accuses the profession of forgetting the uterus and of disturbing the digestion and general health by overmedication. Such has not been my own experience. Through the West I have found they are prone to overtreat the uterus. This gynecological enthusiasm is largely due to the money that is in it. There is no doubt that in many cases it is the pecuniary consideration.

I picked up a piece of paper and noted from memory purely a large number of physicians who have asked me in the last six months to see patients suffering with advanced forms of tubal disease, due or not to, but following immediately the treatment that had been instituted. A physician living a couple of doors from me, Dr. Crandall, has asked me to see six cases which had to be relieved by abdominal section. They had had intra-uterine treatment, electricity, dilatation of the cervix and the like. Dr. John T. Hampton asked me to see three patients that had been treated by a number of men. They had huge pus tubes, and the specimens I have presented to this society. Dr. Logan, of Scranton, brings two cases following closure of the cervix by a distinguished operator; they presented huge abscess. In one of Dr. Hampton's cases I had to remove the appendix in addition to a large abscess and pus tubes. While in Cincinnati three years ago I saw with Dr. Ricketts a woman with the pelvis full and huge pus tubes following intra-uterine treatment. On my way home, I operated on a few similar cases in Youngstown and in Warren, Ohio, all following intra-uterine treatment. Dr. Murfree, of Murfree's Borough, Tennessee, sent to Dr. Eagleton a patient who had been eight years under treatment. She was seen by two gentlemen and both insisted upon section. These are simply typical cases, and I could give many others. I am sorry that Dr. Duer is not here. Eight years ago I sent a patient from the Philadelphia Dispensary to the Presbyterian Hospital to have the cervix closed. I am satisfied that she was free from ovarian and tubal disease. I had myself twice attended her in confinement. Five years later I had to do a section on her for double tubal disease. Dr. DaCosta, in a recent discussion of this subject, calls attention to some of the difficulties following the cervical operation, and in one or two of his cases he had a hard fight to save the patient's life. In the patient of the lamented Dr. Bruen (and it was in watching this friend that he got his pneumonia), I did a section for universal adhesions of everything in the pelvis and everything that could get into the pelvis. This was done six months after a cervical operation. This was only one of four cases following closure of the cervix by the same operator. I have done over thirty sections in one town alone in Ohio for trouble following intra-uterine medication and treatment. Some of these patients I examined two years ago.

On Friday, two weeks ago, I removed the pus tubes which I now show you. Some of these patients have persisted with treatment notwithstanding that I told them two years ago that nothing short of a section and removal of the offending organs would afford relief. I have no longing for such neglected and delayed cases. I have had half a dozen cases from West Chester where the cervix had been closed or dilated. I operated in August on a lady, the wife of a prominent physician in the South. The cervix had been closed a few months before. I operated to save life. Dr. McMurtry, of Danville, tells me that he has had a number of sections of that character. I remember some years ago picking a little woman out of the Midnight Mission and turning her over to one of my pupils for a cervix operation. Three months later he asked me to see her with an angry pelvic inflammation and a huge abscess of the left ovary. He adopted that imperfect method of stitching the sac to the abdominal wall, notwithstanding that I opposed it. The woman died in the Pennsylvania Hos-

pital some months later with the drainage-tube still in. Dr. Norton has presented the specimens here. I was asked some months ago by a physician now present to see a patient with some pelvic trouble following application or dilatation. I insisted upon prompt section. The physician returned with instruments for that purpose, but met with some opposition from the old family physician, which continued for four or five days. The operator then resigned all claim to the patient. I did not see the patient again. I might say here, that once upon a time a man saw the same woman with pelvic trouble and suggested that they wait for a rigor. They waited some three days and the rigor came. He then insisted on an abdominal section and the woman died upon the table. This was nine days after I had urged the section. Dr. Montgomery will remember a young woman, an exceedingly distressing case. She had had every passage, with the exception of the mouth and nose, dilated and cut for a period lasting something over a year, not under Dr. Montgomery's care, however. The urethra had been dilated five times and the cervix many times. She had had many attacks of peritonitis, and some of what were called typhoid fever. She had been treated for cystitis. I found large pus tubes which had followed this treatment. A lady on Darby Road had been treated by twelve physicians. Finally one of them closed the cervix and an abscess followed. This was opened from the bowel. She continued to suffer and demanded an operation at my hands. I made an extensive dissection and resection, and she had the first and only fecal fistula that I ever had follow an abdominal section. This finally closed and she is now perfectly well.

I took a glance at the transactions of the Philadelphia Obstetrical Society and I find four or more deaths reported following the use of tents. Drs. Hodge, Wilson, Willard and Richardson each reported one. Last summer I was called to Trenton to do a section on two women dying with peritonitis. Both had had dilatation or uterine treatment. Some of you will remember a patient of Dr. Daland's, on Pine street, some years ago. Both Dr. Pepper and Dr. Elwood Wilson saw the case. For eleven days she was watched with peritonitis and intestinal obstruction and I was asked on the eleventh day to do a section. The bowel was gangrenous and presented miliary cracks. The trouble followed dilatation. There had been no trouble prior to the dilatation. The operation was done to favor conception. Her sister has since had a section for double pus tubes and ovarian abscess also following cervical and intra-uterine treatment.

One of my assistants took a case out of the Philadelphia Dispensary during my absence and closed the cervix. On my return I found her with an angry peritonitis and huge acute pus tubes. I operated successfully to save her life fourteen days after the cervical operation.

If there were time I could make two or three quotations from Dr. Goodell. You have all read them, and it is scarcely worth while to repeat them. In one of his articles (*Gyn. Transactions*, Vol. iii, pp. 28–31), he says: "Take for instance this too common picture from life. A girl who enters puberty in blooming health." . . . "The treatment goes on and she settles down to a sofa in a darkened room and lapses into habitual invalidism." (See *Transactions of College of Physicians*, Third Series, Vol. xi, 1889, p. 265.) I could give numerous other references from this one author alone, but I have said enough to demonstrate the great mischief done, demanding the promptest treatment possible to save some lives otherwise doomed to be lost. Close analysis by the light of scientific work at the operating table and study of records should be quite sufficient to guide honest, scientific workers, with an honorable motive. I cannot refrain, in closing, from giving a quotation from Sir John Tilt. He says: "America with accustomed audacity . . . . What matters if the cervix does give way with an audible snap, the woman is under ether."

Dr. Daniel Longaker said: It seems to me that if all the cases referred to by the last speaker had come under his observation before the serious symptoms had developed, his position would be distinctly stronger. As it is, however, but few of the cases were seen by him before interference was demanded, and there is, therefore, a certain element of doubt. The only force that the argument has is that the cases were improperly selected—a plea which the author of the paper had already made. I am fully in accord with the reader of the paper. In regard to my own experience with the sound, it has been a matter of great surprise that, in my earlier years, I did not do more harm with it than I did. Once I felt the point of the sound near the umbilicus, but the patient never had a symptom following the

accident. My sound was broken some four or five years ago and I have never bought another.

Some criticism was made on what the reader said in regard to fixed uteri. I think that the author's idea comes in there by implication; *i. e.*, the uterus *per se* is to be left alone and the diseased appendages are to receive attention.

Dr. E. E. Montgomery said: I was impressed with the paper as being an exceedingly conservative one. In many points I am fully in accord with the views expressed. I am not willing to object to intra-uterine treatment to the same degree as Dr. Noble. I am not willing to concede that the cases which have been mentioned by Dr. Price have been necessarily due to improper use of intra-uterine treatment. I am inclined to think that the views of Dr. Price have been largely influenced by the class of cases which he has been called upon to see in the last few years: cases which have been referred to him, and where he has had more to do with the abdominal work than with the other conditions. The extreme views which he holds in regard to this matter have a good influence upon the profession, however, in preventing undue intra-uterine treatment, and the abuse of measures that in many cases are of extreme value. There are some cases which cannot be so quickly relieved by any measures as by careful and judicious intra-uterine treatment. In many cases of uterine catarrh, particularly of the cervix, as we often find complicating laceration, where we find the cervix with a plug of viscid mucus sometimes discolored with pus, blood, etc., in such cases careful cleansing with the use of the curette, applied to the whole cervical canal, and the subsequent application of astringents, or tincture of iodine, or carbolic acid, will relieve the patient very quickly.

It is true that the operation for laceration of the cervix has been greatly abused. I have, like Dr. Price, had to operate on a patient for the removal of the ovaries one or two years, and even three years subsequent to the performance of the operation for laceration of the cervix.

Many of the cases of fixation of the uterus are not necessarily cases to be left alone or treated by abdominal incision. There are cases where the fixation is the result of adhesive peritoneal inflammation as the result of exposure to cold during a menstrual period. In these cases there is not necessarily chronic tubal or ovarian trouble sufficient to require their removal. The reflex neuroses which arise are more the result of the disturbance of the circulation. Such patients subjected to the treatment of Schultze, by manipulation with two fingers in the rectum and one hand over the uterus, have been relieved from distressing symptoms, for which it had been necessary to use morphia. These, however, are special cases. They are to be carefully selected, and we necessarily must treat them as carefully and judiciously before and after the procedure as if the abdomen had been opened. In cases where there is the possibility of pus about the tube or ovary such treatment is objectionable and dangerous.

In regard to the dilatation of the uterus, I wish to call attention to the method suggested to the profession at the International Medical Congress held in Washington, in 1887, by Professor Vulliet. The method suggested was by the introduction of iodoform, or other antiseptic gauze. I have employed this method in a number of cases with valuable results. It may be necessary to reapply the gauze three or four times. By this method the cavity of the uterus can even be explored with the eye. Even this plan of treatment should be used with the greatest caution. The patient should be kept quietly in bed during the treatment. I prefer this method to the mechanical means of dilatation. I believe that there is less danger of injuring the mucous membrane and the tissues of the organ, which must necessarily be bruised and lacerated by mechanical dilatation sufficient to accomplish the purposes usually desired.

Dr. William Goodell said: I listened to the paper with pleasure, for it pleases me to hear so conservative a paper from so young a member of this society. I agree with him almost wholly in every respect. I rarely employ the sound, but I cannot wholly give it up. I think that it is of service in certain cases, for instance, to decide the question of fixation of the womb when the adhesions are slight.

In the past few years I have changed my whole practice in regard to intra-uterine medication. It is now rare for me to swab the endometrium, for I have learned that many of the diseases of the womb cannot be cured by such application, and there is a certain amount of danger attending their use. Leucorrhœa is a symptom which is often not controlled by the most heroic

intra-uterine applications. Like a chronic nasal catarrh it may not do much mischief, and it is often a symptom of nerve prostration. I have, therefore, ceased attempting to cure it by merely local means.

I look upon the curette as a valuable instrument, and should hate to give it up. I have seen no mischief resulting from its use since the introduction of the antiseptic methods. Indeed, in recent years it is rare to see any bad results following any kind of minor surgery.

I am not prepared to go to the extent that Dr. Price has done. If he had said that too many manipulations are made, and that too many surgical operations are done, I should go hand and glove with him. I am sure that the womb is an over-treated organ. I believe that in many cases, perhaps, indeed, in the majority of cases, the womb is treated when it is not the cause of the disease. At the same time I am not prepared to accept the statement that the profession does this for gain; while, of course, a black sheep turns up here and there, I do not believe that the majority of the profession make these applications simply for the money that is in it. They do it through ignorance, and because the womb has been made the scapegoat for almost all of the diseases of women. Again, the physicians are in a measure forced to treat the womb because the women themselves attribute nearly all their ailments to this organ. I think that a good deal of minor gynecology is done by men who should not attempt it, and many of the bad results are due, not to the operations, but to the operators. I am not willing to accept the cases brought forward by Dr. Price, for it is quite probable that in some of them pus tubes were present which were not recognized at the time of the operation.

I have done so much good with the uterine dilator that I should dislike to give it up. There is nothing equal to it for the relief of dysmenorrhœa, or of sterility. I have had over 400 cases of dilatation, and have not seen any serious results, especially since the introduction of antiseptic surgery. Dr. Price has quoted from Tilt in regard to my hearing the cervix snap. I grant that this was rather an extravagant statement, made when I was younger and more enthusiastic. Yet I have repeatedly heard sounds like the parting of muscular fibers, but with only good results, from the operation of cervical dilatation.

Dr. Price has misunderstood a quotation which he has made from my *Lessons in Gynecology* about a young girl going from one physician's office to another's, who is finally doomed to hopeless invalidism. She is doomed—not because the physicians made applications to her womb, but because they did not understand the cause of her trouble, which lay in the nervous system, and not in the uterus. Here lies the great mistake of the modern school of medicine. The womb is brought so prominently into view as a cause for disease that every other organ is overlooked.

In regard to cervical tears, I am sure that we should operate on them. That they are over-operated on I am willing to acknowledge. Yet in selected cases great benefit accrues from this operation. I am satisfied that uterine cancers come, in the great majority of cases, from uterine tears. I do not think that I have seen half a dozen cases of cervical cancers in women who have not borne children. This, in itself, is a strong argument in favor of the operation. Again, out of the hundreds of cases operated on by myself, not one was ever attacked by cervical cancer. Further, grave constitutional symptoms, even threatened insanity, have in my hands disappeared after operations on cervical tears. But one must not promise too much from this operation, else one will disappoint one's patients. I am, however, quite skeptical about the evil effects of the cicatricial tissue sometimes seen in self-healed tears. In my experience, the symptoms attributed to the cicatrix are nerve-symptoms, and are to be cured by treatment directed to the nervous system. There is another advantage accruing from this operation, viz., that retroversion is sometimes cured by it. I have repeatedly seen this good result happen.

There is one statement made by Dr. Noble which I should like to take exception to. That is in regard to the use of the curette for the removal of portions of the placenta and membranes left behind in miscarriages. In my opinion, this is a mistake. Yesterday I had at my clinic a woman who had a miscarriage three months ago, and since then has had continuous oozing, occasionally amounting to free bleeding. I said to the class that evidently some placental tissue was retained and had a vital attachment to the womb; but that I would show them, practically, that the curette was not the instrument to use, for it would merely dislodge the placenta without removing it, and large

uterine sinuses would then be uncorked, as it were, by it, causing a serious hemorrhage. Sure enough; as soon as I had begun to use it so large a stream of blood poured out that I had to thrust my finger into the canal to plug it up. I then made haste to use the instrument par excellence for this purpose—a fenestrated polypus forceps—and in less than a minute removed a placental fragment as large as the first joint of my thumb. The curette is useful for the removal of fungoid vegetations of the endometrium and for villous exaggerations occurring at the placental site, but not for bulkier bodies.

As I have already said, I was much pleased with the paper, and I was also with the remarks of Dr. Price. He is doing good to the profession and to all of us by calling attention to remote results of uterine treatment. At the same time, I cannot go with him so far as to attribute all the cases he has brought forward this evening to the use of the curette, intra-uterine medication and dilatation.

Dr. John C. DaCosta said: Dr. Goodell has expressed so clearly what I feel on this subject that but few words are necessary.

First, in regard to the sound. I have examined a great many women and have often used the sound, oftener in past years than recently, and am not conscious of having done mischief with it. There are certain uterine conditions that you cannot diagnose accurately without the use of the sound. By palpation you can explore the exterior of the uterus and usually determine whether or not it is adherent. Take, however, a womb like this sketch, apparently normal in shape. But the patient is bleeding and you want to know the cause. The womb may be a little enlarged; but yet we see large wombs that do not bleed and are not diseased. The cervical canal may appear to be healthy. There is something inside that womb, but bimanual palpation will not tell you what it is. Introducing the sound, you will find that instead of passing normally, the instrument meets with obstruction. This cannot be discovered by bimanual palpation. You use your sound and find a fibroid bulging in the anterior or posterior wall. Here is a case that needs treatment, and you cannot treat the patient without getting inside the uterus. To be sure, you can (as has been suggested) remove the tubes and ovaries, but a woman does not want the tubes and ovaries removed when she can be cured by other measures, and you do not want to do it.

I have expressed my views in regard to the curette in the discussion of the paper of Dr. Price on "Major Pelvic Troubles due to Minor Gynecology." I should be loth to do without the curette. In using the curette a man should know his work. Many of the troubles referred are due to men undertaking work that they are not fitted for. There is probably nothing that requires more careful training than minor gynecological practice with, perhaps, the exception of abdominal surgery, and that major troubles may follow minor gynecology is due probably to the fact that men attempt minor gynecology who do not understand it. In cases coming to the clinics and handled by unskilled men without due regard to the conditions present, there may be unnecessary operations performed, and operations may be performed where there is unrecognized tubal or ovarian disease. Not so, however, when men know their business, and are experienced in the treatment of cases.

I cannot accept all of Dr. Price's cases. He mentions a remark of mine, that "I had to fight for the life of a woman after an operation on a lacerated cervix." Well, so I did, and won the fight, and she has been a well woman ever since. That was before the day of aseptic surgery, and I am not satisfied that the trouble did not originate from sepsis. In operations on the torn cervix I have often found, as Dr. Goodell has stated, that the flexion that is present has been relieved. This was markedly shown in a case operated on by me last week. Before the operation there was a very sharp flexion; after it, the uterine canal was normal in shape.

Some seven or eight years ago, in the discussion of a paper of mine on laceration of the cervix, Dr. Goodell stated that it was rare to find cancer of the cervix except in cases with a tear of the cervix. Since that I have borne this point in mind, and have not since then seen a case of cancer of the cervix where there had not been a tear. Many tears do not require operation; they will get well by rest and attention to the general condition. Others will not, and operation is the remedy to cure and prevent danger in the future.

I have used sponge tents frequently, both the ordinary sponge tents and those with watch springs in them. Dr. Ellerslie Wallace told me that he had lost a case from the use of sponge tents and told me the reasons, and bearing in mind the reasons, and avoid-

ing means that would cause danger, there has been no trouble with them. Sponge tents are like a surgical instrument—you must know when and how to use them, and to get results must know how to make them and must make them yourself. The ordinary sponge tents as sold in the shops are useless and even dangerous.

The dilator is too good an instrument to be lightly given up, and, like any other surgical instrument, while achieving grand results in able hands, it is a dangerous tool in careless or unskilled hands. Choose your cases for it, and you will never regret using it. But remember also, that every bent womb does not need a dilator.

As to the money influence that Dr. Price alluded to, I should be sorry to think that the members of the profession are influenced by the pecuniary consideration. I could tell some touching tales about the money influence on the other side in patients who have at times come under my own care.

I do not think that the mortality of minor gynecology is as great as Dr. Price has led us to believe. It is certainly, so far as I have been able to ascertain, nothing like the mortality from unwarranted abdominal surgery. Probably a good deal of the difference in ideas is due to a difference in the class of patients.

Dr. C. P. Noble, in closing the discussion, said: I am glad that this paper elicited such a full discussion, and that in general the criticism has been so kindly; but some of the speakers have misunderstood me. It might be inferred, from what Dr. Price has said, that I believe chronic cellulitis to be a frequent pelvic condition. The terms cellulitis, fixed uteri, and the like, are in quotation marks in the paper. The whole tone of the paper shows that I do not regard cellulitis as a common condition.

What I would say in reply to Dr. Price has been so well covered in the discussion by other speakers that it is not necessary for me to say anything. It is probable that in many of the cases reported by Dr. Price the tubal or ovarian disease was present prior to the minor operation or treatment employed; and in order that these cases should have a bearing upon the argument, an exact diagnosis should have been made before treatment was begun. These cases come under the category which I referred to in the paper as cases in which minor uterine surgery is not indicated. Again, women who have been subjected to minor uterine surgery are liable to suffer, later, from gonorrhœa or other causes of salpingitis. This fact doubtless accounts for some of the cases reported by Dr. Price.

In regard to what I said about fixed uteri being left alone, the context clearly shows what is meant. The idea is that the sound should not be used for repositing the fixed uterus. This class of cases are really not uterine. I agree with Dr. Montgomery that in rare instances, when the adhesions are light and the Fallopian tubes are comparatively healthy, the uterus can be freed by careful treatment; but, in general, fixed uteri are fixed because of tubal and ovarian disease, with peritonitis. In the cases referred to by Dr. Price, the uterus was left alone and he removed the real source of trouble, the diseased tubes and ovaries.

I agree perfectly with Dr. Goodell with reference to the use of the curette in miscarriage. The curette is not the instrument for the removal of portions of the placenta. I prefer to give an anæsthetic and to use my index finger as dilator and curette. In no other way can it be known when the uterus is empty. The results have been so satisfactory that I have not had occasion to use any instrument. In most cases of incomplete miscarriage the pregnancy has advanced to or beyond the third month. When miscarriage takes place earlier, the ovum is usually thrown off *en masse*, or in the earliest weeks as detritus. Under these circumstances manual interference is seldom if ever required.

In the paper I said nothing about the use of the dilator or curette in the office. I think that this practice should be unqualifiedly condemned, because proper antisepsis cannot be employed under the circumstances, and because dilation and curetting cause too much pain to be done efficiently without an anæsthetic.

PERISCOPE.

Koch and the German Government.

The British Medical Journal of January 10, 1891, says editorially: During the last fortnight various rumors have been telegraphed from Berlin as to the arrangements made, or about to be made, between the German Government and Professor Koch with regard to the future production of his remedy for tuberculosis, and it must be ad-

mitted that these rumors have been of a somewhat disquieting character. It has been said that Dr. Koch, and each of his assistants, had accepted a large immediate payment, and that they were to receive a royalty upon all sales in the future. Thus stated, the arrangement, it must be admitted, would partake far too much of the commercial transaction to be agreeable to the traditions of the medical profession, or the customs of men of science. It is, however, easy to give an unfavorable complexion to a transaction really of an honorable nature by inverting the steps by which the final results have been obtained and so misrepresenting their character. It may be well to recall the circumstances under which the lymph has been discovered, and the position of Dr. Koch in relation to the German Government. Dr. Koch has been for many years the director of the Hygenic Laboratory in Berlin. This laboratory is a Government institution, maintained by the Educational Department of the German Government, and Dr. Koch, as its director, has been an officer of that department. All the earlier experiments for the discovery of the now famous lymph were conducted in Dr. Koch's own laboratory in the Hygenic Institute, and there the observations upon guinea-pigs and other animals, which emboldened Dr. Koch to proceed to inoculate human beings, were made. The laboratory, however, presented no facilities for making these investigations upon human beings, and Dr. Koch holds no official position with regard to any of the Berlin hospitals. He therefore found himself in a practical dilemma, inasmuch as if he were to make his experiments in a public hospital it was feared that the premature and eager discussion of incomplete observations and immature results might easily tend to interfere materially with the investigations and to produce evil results. Dr. Koch consequently hired a private house at his own expense, and obtained the assistance of two gentlemen with whom he had private acquaintance—Dr. Libbertz, an old schoolfellow, and Dr. Pfuhl, his own son-in-law. The lymph was prepared in considerable quantities in this private house by these two gentlemen under Dr. Koch's supervision, and the earliest injections in man were made in the private hospitals of Drs. Cornet and Levy. It soon became evident, however, that the interest, both among the general public and in the medical profession, was too keen to permit of the continuance of the investigation upon these lines; and Dr. Koch, acting on the advice, or perhaps it might be correct to say upon the instructions, of Herr von Gossler, the Minister of Education, published the now famous preliminary paper, and distributed the lymph to certain of the hospitals in Berlin. Meanwhile, the manufacture of the lymph was carried on in the private house by Dr. Koch and his two personal private assistants. Recently this arrangement has ceased; the house in which the lymph is manufactured has been taken over by the Educational Department of the German Government, and Drs. Pfuhl and Libbertz have become officers of that department. The Koch Institute, which the German Government are now erecting, will consist of two parts—a laboratory and a clinical department containing 150 beds. The clinical department will probably be under the direction of Professor Brieger. The observation and treatment of the patients received into it, it is hoped, will afford in the future opportunities for Dr. Koch to prosecute his studies with regard not only to tuberculous diseases, but to tetanus, diphtheria, and typhoid fever. In this way the inconvenience which has arisen from his having no clinical wards of his own will be avoided.

In the laboratory bacteriological investigations will be carried on, and at the earliest possible date the laboratory for the preparation of the anti-tuberculous liquid will be transferred to this department of the Koch Institute. The director of this bacteriological department has not yet been appointed, but the whole institute will be under the general direction of Dr. Koch, who will remain an officer of the Educational Department. It is probable that the German Government will offer to Dr. Koch some recognition of the great services he has rendered while acting as a German official, such as was voted to Jenner for his services in a cognate research, and more recently to Pasteur, in France. Large national awards have repeatedly been made to successful generals in Germany and in other countries, and it is felt that there is no reason why a man of science, who has worked for the relief of human suffering, should hesitate to accept a reward which the destroyers of men have never felt the least difficulty in receiving. As to the further rumor that Dr. Koch and his assistants may receive a payment as it were by results in the future, it may be hoped that this rumor

is unfounded. Anything like the sale of a secret or the paying of royalties on a remedy would be contrary to the Hippocratic tradition.

Cerebral Tumors.

Dr. P. C. Knapp, in the *Boston Medical and Surgical Journal*, January 8, 1891, says Oppenheim reports twenty-three cases of tumor in the cerebrum, with a careful analysis of the symptoms. Eighteen of these were gliomata or sarcomata, three were cancerous, one tubercle, and one gumma. Only striking cases in adults, however, are admitted to the hospital. In three cases a diagnosis of tumor was not made, and in three others it was at first doubtful. Oppenheim lays great stress on the importance of frequent examination of the eyes, even up to a short time before death, for choked disc may be a late symptom; he also distinguishes between choked disc and neuritis. The changes in the nerve are of the utmost importance in diagnosis, and are of very frequent occurrence. In nephritis, however, the ophthalmoscopic picture may be that of neuritis, the retina showing no changes. In such cases, where there is uræmia or cerebral hemorrhage, with a negative urine, the diagnosis may be very difficult. He holds that neuritis or choked disc is absent only in those cases where the intra-cranial pressure is only slightly increased. Next to changes in the optic nerve, stupor and somnolence are of great value in diagnosis. It is sometimes difficult to keep patients awake long enough to answer questions. Oppenheim then analyzes the cases to learn how far focal symptoms can be relied on for diagnosis. In twelve cases there were aphasic symptoms, in nine of which the left temporal or frontal lobe was involved. An exact focal diagnosis could not be made from the symptoms, however, as the seat of the growth did not correspond to the particular type of aphasia, and some of the tumors were in the basal ganglia. In two cases the tumor was in the right hemisphere, and in one of these the patient had become left-handed at the age of seventeen, which raises the interesting question as to the possibility of the transfer of the speech centre in youth. The same may be said of the value of motor symptoms in diagnosis. In a few cases the new growth affected the precise centre corresponding to the disturbance of motion, but in others the tumor proved more or less remote from the centre, or deep down near the basal ganglia. With the uncertainty that still obtains in regard to the localization of the sensory centres, it is obvious that sensory disturbances give no more exact information than motor. Local headache is an entirely untrustworthy indication of the position of a tumor, but localized tenderness on percussion has greater value. In four of these cases was a more or less accurate focal diagnosis possible, and operative interference could have been undertaken—about seventeen per cent. In view, however, of the uncertainty that still obtains in diagnosis, of the limited success that recorded operations thus far show, and of the small percentage of cases that can be operated on (it must be remembered that, in this paper, Oppenheim deals only with tumors of the cerebrum itself), he considers that operative interference has a very limited field.

Physiological Action of Thialdine.

Thialdine, obtained for the first time by Woehler and Liebig, in the form of large crystals, of aromatic odor, which volatilize at the ordinary temperature without decomposing, is but slightly soluble in water, dissolves rapidly in alcohol and acids. According to *Les Nouveaux Remèdes* for November 8, 1890, from experiments made with this substance the following conclusions were reached:

1. Thialdine is very poisonous in frogs in the dose of ⅓ grain for every one hundred and fifty grains body-weight, though much less poisonous in rabbits.

2. Its administration is followed in the frog by profound sleep, with loss of general and reflex sensibility, depressed sensibility of the motor nerves, while the muscular irritability remains intact. In the rabbit the anæsthesia is less intense, and interrupted by excitation.

3. Thialdine invariably causes slowing of the pulsations of the heart, which, nevertheless remain perfectly regular. It is only when given in very large doses, and then only immediately before death, that the pulsations of the heart become irregular.

4. When given in small doses, the slowing of the pulse is only transient. Injected in small doses in the excised heart, thialdine diminishes the number of pulsations, at first prolonging the diastole, after rendering the

contractions of the heart irregular and more rapid, and finally arresting the heart in diastole.

5. In large doses it slows at the outset cardiac contractions, and then leads to the arrest of the heart in diastole.

It would thus seem that carbo-thialdine and thialdine differ absolutely from each other as regards their physiological action. The first is an energetic tetanizer, and never produces irregularity of the heart, which it arrests in diastole. On the other hand, thialdine produces irregularity of the heart, which, in the majority of cases, it arrests in systole; finally, while carbo-thialdine produces no effect on rabbits, thialdine is poisonous in them, though to a less degree than in frogs.—*Therapeutic Gazette*, January, 1891.

Chloroform as an Antiseptic.

The *Lancet*, December 20, 1890, says, Salkowski has demonstrated as the results of his experiments that chloroform prevented fermentation and decomposition in milk and other fluids. M. Kirchner (*Zeitschr. für Hygiene*, viii, 1890, Heft 3) has also made some investigations in regard to this property of chloroform. He first showed that, when mixed with blood serum, no decomposition of the latter occurred, and then further showed the same action on milk, and also its purifying properties on waters known to be rich in bacteria, and, again, on pure cultures of pathogenic and non-pathogenic organisms. The method employed was as follows: Chloroform was added in excess to the fluid to be experimented on; the vessel in which it was contained was then hermetically sealed and thoroughly shaken. The various specimens were kept at different temperatures—namely, that of body or air, or in an ice chamber. The contents were tested after variable periods of time, lasting from hours to years, by means of plate cultivations. The results obtained were that chloroform has a powerful destructive action upon a great number of bacteria, but does not kill their spores. The bacilli of anthrax, cholera and enteric fever, as well as the staphylococcus aureus, were quickly destroyed by chloroform. The spores of the anthrax, and tetanus bacilli were not affected by the drug. In spite of its presence the spores developed into bacilli, which were then rapidly killed. Kirchner considers from these results that milk to which chloroform has been added can be preserved for a long period, although we cannot be sure that it is free from spores which will eventually develop. Kirchner recommends its use for the preservation of fluids containing albumin, and especially for sterilizing blood serum, the composition and coagulating power of which are not appreciably altered by its presence, and its use as a cultivating medium is not influenced. The mixed fluids are best preserved at the ordinary temperature of a room and not in an ice chamber. Kirchner further recommends chloroform water for the disinfection of wounds, and states that it is especially useful in gynecological and obstetric practice, and also for the disinfection of bed-pans, linen, etc., in epidemics of cholera and typhoid fever. He supports Salkowski's views as regards its favorable action on some intestinal affections, especially the diarrhœa of children. He also advises that it should be used in military campaigns for the purification of drinking water.

A Ready Inhaler.

In the *British Medical Journal*, November 22, 1890, Mr. Arthur H. Rideal gives the following description of a ready method of arranging what he says is a most effective inhaler. Take an ordinary funnel, and in it loosely pack some cotton-wool. On this sprinkle the medication (ol. eucalypti., etc.), and then tie a piece of gauze or muslin over the funnel to keep the wool in position. Invert the funnel over some hot water contained in a breakfast cup, or other vessel, according to the size of the funnel, and an inhaler is obtained which is equal, as regards its utility, to the most elaborate.

Detection of Bile Pigment in Urine.

The *American Journal of Pharmacy*, December, 1890, says that bile pigments may be detected in urine as follows. Slightly warm about a fluid drachm of the suspected urine, and add 5 to 10 drops of tincture of iodine, agitating after the addition of each drop. In the presence of bile pigments, a pretty olive-green coloration is produced. Excess of tincture of iodine will produce a dirty brown-red color. Normal urine at first decolorizes the iodine solution, then gives a red coloration, and on addition of an excess of iodine a dirty brown-red color.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

KOCH'S METHOD.

The developments in regard to the Koch method for tuberculosis within the past two weeks have not been of a very striking character. The medical journals in different parts of the world continue to produce publications about it, some of which are of the usual non-committal sort, some are hopeful, while some claim that characteristic reactions and apparently reliable improvements have been brought about by its use. In Philadelphia there is nothing novel in the recent reports in regard to the remedy. Some of the patients at the Philadelphia Hospital (Almshouse) consented to be experimented upon with it, but we have not heard of the result. At the University Hospital experimentation is continued in a cautious manner. Dr. Musser, who has charge of the medical experimentation there, made a public address on Friday, January 23, and is reported as expressing considerable confidence in the value of the remedy, saying "It was valuable not only in reaching and relieving particular diseases, but opening a new path to medicine, showing how cures were wrought, and developing new methods of treatment." The University of Pennsylvania Commission reports its experience in the number of the *University Medical Magazine* for February, but there is nothing special in it. The Johns Hopkins report in the *Bulletin* of the Hospital, January, 1891 (just issued), gives no new ground for confidence in the diagnostic or therapeutic value of the "lymph."

It is with some regret that we notice that under various titles, institutes have been started in New York City, which advertise that they are what might be called "Koch Institutes" or Sanitariums. One of these has connected with it the names of Dr. George F. Shrady, editor of the New York *Medical Record*, Dr. H. P. Loomis and Dr. W. C. Wendt, who advertise that a limited number of patients can receive the Koch treatment at a private sanitarium in New York. It is rather hard to reconcile the participation of Dr. Shrady in this enterprise with some of the editorials which he has published on this subject—although the first number of the *Medical Record* in which we notice this advertisement, contains rather glowing accounts of the experience by Dr. Wendt and Dr. Shrady in the use of the Koch remedy—or to understand the scientific or ethical basis upon which an institution advertising to treat patients by an exclusive method can rest. We had hoped that it would be impossible, even in New York, to have institutions of this kind organized, except by persons well known to the profession, as inclining to this way of securing notoriety, and we hope the example set by the men named above will not find imitators elsewhere.

The news from Berlin, under date of February 1, was that Professor Koch, who was about to start for Egypt, had given a fare-

well reception to his laboratory assistants that day. In this he said that he would probably be absent from Berlin about three months. He explained that he only partially disclosed the method of the production of the curative lymph, because he desired to stop the rush of doctors to Berlin (!). If he had described the method of manufacture more fully, he says, he would have been more worried about the details. The Berlin report stated that great discontent prevailed among medical men regarding the published accounts of the method of manufacture of the lymph. They had made numberless attempts to produce the lymph, but they find Koch's description totally inadequate to enable them to make it.

SECRET REMEDIES.—KOCH'S REMEDY.

The *Medical Press and Circular*, of London, in its issue for January 14, discusses editorially the curious state of medical ethics into which the use of Koch's then entirely secret and now only partially explained remedy has plunged the world. The tolerance shown to Koch in his secrecy and to those who used and exploited his so-called remedy, is contrasted with the principles which have been supposed to govern the medical profession. "The fact," our contemporary says, "is, matters are getting critical. The censors of the Royal Colleges of Physicians are fidgetting in their curule chairs, having been made uncomfortable by the feeling that it is due to the dignity of the bodies of whose honor they are *pro tem.* the custodians, and to consistency, to condemn, and, by condemning, to prohibit, further experiments with a remedy which is not only secret but dangerous—not only dangerous but, so far as our knowledge goes, therapeutically indifferent. Why, indeed, do the censors stay their hands? Is it because their correction would fall upon some of the best known and nosiest of the tribe of influential self-advertisers? These modern Jupiters apparently reserve their thunderbolts for little people, and at most mildly expostulate when the sinners are men occupying a position well in view in the medical world. These, however, are democratic times, and if the censors fail to enforce the rules of professional etiquette on this occasion they may as well retire into private life. Humbler men, encouraged by the latitude accorded to their seniors in the professional hierarchy will raise their drooping heads and set salutary discipline at defiance. The policy seems to be to postpone action until the 'boom' is over and the agitation has died a natural death. This may be politic, but it is not justice or equality. In face of the evident determination of the Germans to keep the secret of Koch's discovery, it behooves us to set our faces against any further meddling with a fluid of doubtful value and certain danger. The medical journals ought to speak out in no uncertain tones before the evil, already great, becomes a positive scandal."

The REPORTER has spoken out, at the very first announcement, and consistently ever since. If its example had been followed by all the other medical journals, the most famous bacteriologist of our times would perhaps have had courage to resist the strong and unprincipled pressure of the German Cultus-Minister, von Gossler, to do for national pride what is opposed to professional principle.

THE MICRO-ORGANISM OF MALARIA.

When, in 1884, Laveran published his treatise on *Paludal Fevers*, and announced his discovery of certain peculiar parasites (plasmodia) of infusorial order in the blood of patients in intermittent fever, his announcement was at first received with indifference and scepticism. Microbiologists were just losing all faith in the etiological relation to malaria of the bacillus discovered four years before by Klebs and Tommasi-Crudeli, although the discovery of these investigators at first awakened great confidence and enthusiasm. It is not our present purpose to give a history of the researches of

these last named experimenters, or to state the reasons why the claims which they so confidently made have been rejected by all competent authorities, as the whole case has been well stated by Sternberg in his treatise on *Malaria and Malarial Diseases*, by Councilman, Osler, James and others in this country.

On the other hand, during the past six years evidence has been accumulating, from all parts of the world, confirmatory of the results obtained by Laveran, and there is largely the same kind of evidence that the plasmodium discovered by him, in 1880, is the infectious agent of intermittent fever, as there is that Koch's bacillus is the cause of tuberculosis. We can only mention here among those who have made careful researches in this direction and have arrived at conclusions, in the main, substantiating Laveran's claim, the names of Marchiafava and Celli, Councilman, Osler, Sternberg and James, Straus, Bouchard, Golgi, Dockmann, Richard, Chassin, Mariotti, Ciarocchi, Vandyke Carter and Metschnikoff.

One thing seems to have been settled, malaria is not a bacterial disease. The most of the infectious diseases whose living agents have thus far been discovered are due to vegetable parasites of the order of fungi; the pathological processes engendered by bacteria are akin to the ravages of the mold, the rot, the mildew. The micro-organism of malaria is of the order of protozoa, and resembles the amœba. In the words of James, there takes place in the blood of persons suffering from malarious disease a series of phenomena not yet found under any other conditions—these phenomena point to the presence of an animal parasite. The appearances which are obtained are the following:

1. Colorless protoplasmic bodies inside the red blood corpuscles. They vary in size from one-fifth to almost the whole diameter of the corpuscle. They exhibit active amœboid movements. Some contain scattered granules of brownish-black pigment; others are unpigmented. The red corpuscle which contains the amœboid body gradually becomes pale by the loss of its hæmoglobin, which is converted by the parasite into the pigment granules above mentioned.

2. Disk-shaped bodies of colorless protoplasm, which are motionless. These are believed to be the plasmodia above mentioned, which have destroyed (eaten up) the blood corpuscle, and have entered on the cyst stage. They contain pigment granules.

3. Forms similar to the cysts in which the pigment granules have become massed at the centre, while the protoplasm is undergoing segmentation.

4. The small masses of protoplasm that have resulted from segmentation of the cyst-form. They are apparently ready to enter upon active work.

5. Certain hyaline crescentic bodies, which Laveran regards as a part of blood corpuscles which have been invaded and partly destroyed by the parasites. They have pigment granules in their centre.

6. Certain flagellated bodies. These are round, pear-shaped bodies about one-half the diameter of a blood corpuscle containing pigment granules and provided with from one to four flagella, which have an active slashing motion. By means of these flagella, the organism moves about in the blood plasma.

7. Free flagella. These have become detached from their bodies, and seem to be capable of leading an independent existence. This flagellum, which has been seen by numerous observers, and which is only a part of the real parasite, has been identified by some authorities with the *bacillus malariæ* of Klebs and Crudeli.

All attempts to cultivate these parasites (hematozoa) outside of the body have failed, nor can malarial disease be induced in the lower animals (though it has been in man) by injecting into the veins blood charged with these micro-organisms.

According to Golgi, the relationship be-

tween the cyclical evolution of the hematozoa (called by him *sporozoa*) and the mode of sucession of the paroxysms (ague fits) is subject to the same vigorous laws which we know governs the disease with which these micro-organisms are associated. In quartan ague, there are exactly three days between the invasion of the red globules by the parasites and the segmentation which the latter undergo to form the young elements destined to a new invasion of the red globules; in tertian fever, the cycle is two days. These differences of evolution correspond to differences in the nature of the parasites; for there are two distinct species of sporozoa, distinguished by their morphological and biological characteristics. The parasites of tertian fever have much quicker amœboid movements than those of quartan. They decompose hemoglobin much more rapidly and more completely; they disintegrate the red corpuscles, while the parasites of quartan fever only cause them to atrophy.

There has been much interesting discussion respecting the divers forms manifested by this polymorphic parasite, and their relation to the various phases of malaria. Thus many authorities believe that the crescents and the bodies allied to them belong to chronic cases, usually to those associated with malarial cachexia. In James's cases, the amœboid forms, pigmented and unpigmented, as also the flagellated forms, were peculiar to the acute stages of the disease.

As for the agencies which destroy the hematozoa — as might have been expected, sulphate of quinine is the most effective parasiticide. The effect of this remedy in arresting all amœboid movements when added to infected blood on the microscopic slide, and in causing the disappearance from living blood of the micro-organisms when the quinine is given in sufficient doses internally, is most marked. But apart from remedial agents, the leucocytes maintain a constant and often successful struggle with the invading foe, and Dr. Vandyke Carter, in a recent communication, graphically describes what he has witnessed in malarial blood — the war between the micro-organisms of malaria and the leucocytes. He has noticed that the crescentic bodies are not so attractive to the leucocyte as the flagellated; for the leucocyte will turn from the former, leaving them untouched, and prey upon the latter. In the fierce combat between the leucocytes and the flagellated spheroids the leucocytes seem often to triumph in the complete overthrow of their adversaries.

The micro-organisms above described resemble much certain flagellated organisms found by Danilewski in the blood of frogs, turtles, lizards and birds. As for their constancy in malarial blood, Laveran has found them in 432 cases out of 480 which he has studied from this point of view, and he thinks the negative cases explicable by unseasonableness or incomplete methods of examination; in a few the blood was examined when the patient was under the influence of quinine. Councilman states that he has noted the presence of hematozoa in all the cases of paludal fever which he has examined, and he has never found them in healthy subjects, or in persons affected with other diseases.

Laveran has sought for the parasite of malaria in the water and soil of infected localities. He reports the discovery of free flagella presenting almost the same aspect and dimensions as those found in malarial blood, and animated by the same movements; also of spherical flagellated bodies similar to those above described. Of course (as Hallopeau remarks) they cannot be considered *identical* until paroxysms of genuine intermittent shall have been produced by inoculating the blood of human beings with these infusoria of the marshes.

As stated in the Reporter, January 3, page 28, Danilewsky has recently stated that he has seen venti malaria in birds, with the characteristic parasite, and believes that this establishes the identity of the disease in them and in human beings. This curious and important subject is still being studied

by a number of able investigators and the facts in regard to it are accumulating in a manner to justify the hope that the doctrines in regard to it may before long be clearly understood and precisely formulated.

CLINICAL LECTURES.

In the preparation of Clinical Lectures for the REPORTER, it has been the rule that nothing should be printed which had not been revised by the lecturer, in manuscript or in proof, and approved for publication. In this way we have been able to present to our readers a series of very valuable and authoritative communications from some of the most able teachers in the country. Accidents will happen, however, and in consequence of the mislaying of proof-sheets, a lecture delivered by Dr. J. H. Musser, and published in the REPORTER for January 24, did not contain the corrections which he wished to have made in it, and any inaccuracies which it contains are, of course, not to be attributed to him. We publish under the head of Correspondence a note from him on this subject—in justice to him; in justice to the REPORTER we may add that the accident which has happened was not due to the omission of any of the precautions customary in the editorial office of this journal.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

STRICTURE OF THE RECTUM. A STUDY OF NINETY-SIX CASES. By CHAS. B. KELSEY, M. D., Professor of Diseases of the Rectum at the New York Post-Graduate School and Hospital, etc. 8vo, pp. 46. (To be had of the Author.)

Dr. Kelsey gives, in this brochure, an instructive essay on stricture of the rectum and its treatment. In speaking of the diagnosis, he declares the idea, deeply rooted in some minds, that stricture of the rectum is either cancerous or syphilitic, is founded on error. Besides cancer and venereal diseases as causes, he describes strictures, according to their etiology, as congenital, spasmodic, due to pressure on the gut, dysenteric, tubercular, inflammatory, and traumatic. He describes treatment under the following heads: Dilatation; Incision; Partial Destruction, including Electrolysis and Raclage; Excision; Colotomy; General treatment.

By dilatation he means gradual stretching, not forcible divulsion. He finds it most applicable, in cases of limited severity, as a supplement to the treatment by incision or excision. Incision alone does not radically cure, but as a means of saving time and of gaining a wider passage than can be hoped for from dilatation alone, Dr. Kelsey thinks it of great value. Partial destruction, electrolysis and raclage are spoken of as examples of timid and meddlesome surgery.

With regard to excision he speaks hopefully but cautiously. One rule, he thinks, may be considered established—cancer should not be attacked with a knife unless there is reasonable certainty that it can all be removed, and that the lymphatics have not become involved to any extent. The method of procedure in excision of the rectum is described. Of the operation of colotomy Dr. Kelsey speaks highly, and he has had considerable experience. He differs from most of the older authorities in preferring inguinal to lumbar colotomy. As regards ease and certainty of performance, the subsequent cleanliness of the patient, and the ability to care for the opening, all the advantages, he says, are in favor of the inguinal opening. He has done the operation eight times, with six recoveries and two deaths.

The paper is an important contribution to surgery of the rectum, and Dr. Kelsey has done a service in writing it.

A TREATISE ON THE DISEASES OF INFANCY AND CHILDHOOD. By J. LEWIS SMITH, M. D., Clinical Professor of Diseases of Children, Bellevue Hospital Medical College, etc. Seventh Edition, thoroughly revised. With fifty-one illustrations. 8vo, pp. xiv, 868. Philadelphia: Lea Brothers & Co., 1890. Price, $5.50.

The appearance of a seventh edition of Dr. Smith's Treatise on Diseases of Children, indicates the exceptional activity which prevails in this special field of medicine. Dr. Smith writes that, since the issue of the sixth edition of his book, in 1886, so many additional facts have come to light relating to the etiology, nature and treatment of the diseases of children that the necessary revision has produced virtually a new book. Such a statement is all the more remarkable when we bear in mind that almost the same words were used by the author in his preface to the sixth edition, which appeared less than five years ago.

Dr. Smith's Treatise is so well known as a standard American work on the diseases of children that an extended review of it is unnecessary. The present edition, its author thinks, may be considered to have doubled in size, so far as the amount of information presented is concerned. He has endeavored to exclude all obsolete material, and to condense the text to the limit of clearness. The number of pages is not much greater, the new material having been accommodated by lengthening and widening the printed page, and using a somewhat smaller type. The effect of this change, so far as the eye is concerned, is not pleasing, but perhaps it is better than running the risk of making the volume bulky.

The present edition contains articles on the following subjects which were not treated in the former edition: Conjunctivitis, Icterus, Sepsis, Umbilical Diseases, Hæmatemesis, Melæna, Sclerema, Œdema and Pemphigus of the new born; Epilepsy, Tetany, Appendicitis, Typhlitis and Perityphlitis. There is also a paper on Intubation, by Dr. Joseph O'Dwyer.

In its present form the book is more compendious than formerly, but its practical value, as a trustworthy guide to the diagnosis and treatment of diseases of

children, has not been diminished. We congratulate its author upon having kept abreast of times which are remarkably prolific of discoveries in his special field, and cordially recommend the book to our readers.

CORRESPONDENCE.

Clinical Lecture by Dr. J. H. Musser.

To the Editor.

Sir: Kindly do me the justice of stating in your journal, that through an accident the Clinical Lecture by me, published in the Reporter, January 24, did not contain the corrections I had made on the proofs. I would not like to be held responsible for its inaccuracies and the erroneous statements regarding the classification of anemia. I do not hold to such classification and could not have made it.

Yours truly,
J. H. Musser, M. D.

Philadelphia.

QUESTIONS AND ANSWERS.

[In this department will be published questions on any medical subject by readers of the Reporter, and answers by the Editor or by other readers.]

What is the Best Stimulant in Impending Collapse?

Dr. W. H. Burr, of Wilmington, Del., writes: I do not wish to have the reputation of being a voluminous writer, but reading medical journals stimulates inquiry. I would like to have from some of your readers a short, scientific and at the same time practical method of treating persons in impending collapse from whatever cause, founded on good physiological reasons or experience, or both.

A good example to work on is the case of a patient exhausted by previous disease who is compelled to undergo a serious operative procedure as an only chance to save life. We have here three elements to combat. Exhaustion from previous disease, shock from operative procedure and anæsthetic influence. What drugs, if any, either by stomach, rectum or hypodermically, are most efficient to help tide the patient over the emergency? One author says alcohol finishes those who escape the anæsthetic effect; another prominent author uses alcohol very freely, and proves his theory by an experience covering thousands of cases. One author recommends hypodermic injections of ammonia, but does not say what form should be used, how much may be used or what the chances of abscesses are. Another recommends digitalis, but is equally reticent as regards quantity, physiological action, etc.

Let some one make a list of all diffusible stimulants which have an action on the vital centers. Let the list include alcohol, morphia, atropia, digitalis, strychnia, nitroglycerine, ammonia—most of these being, by the way, powerful poisons in doses of any great magnitude, and all differing among themselves in their ascribed physiological actions. From this list let there be some plan evolved, resulting in the use of one or more than one of these drugs, so that the defenceless subject may not be liable by well-meant, but ill-directed efforts to be overwhelmed by a multitude of powerful drugs indiscriminately applied.

For humanity's sake let there be a little more method in medicine.

NOTES AND COMMENTS.

The Koch Remedy in New York.

The January number of the medical journal called the *Post-Graduate*, the journal of the New York Post-Graduate School, says:

"There have been some grotesque and almost ludicrous incidents in the Koch excitement. The race to get and use the lymph before others; the suspicions raised, in one instance at least, that the lymph was not Koch's at all; the apologies of an ex-president of the Academy because his name was so much in the papers, and of the president himself, for his son, who was said by a *Herald* reporter to have given an enormous money value to a vial of lymph; the red-colored postals of the County Society announcing as 'Notice Extraordinary' that one of its members was about to tell what he saw in Koch's laboratory—all these things would make a graphic picture of medical New York in a ferment in the latter part of 1890. . . . ."

And again: "The dear old code, for which the New York State Medical Association was born, and in defence of which every member of the American Medical Association is supposed to be willing to die, has suffered dreadfully as a result of Koch's discovery. The whole medical profession throughout the civilized world has been en-

gaged in using, or in endeavoring to use, a secret remedy. We might expect this in lax New York, but in strait-laced Connecticut it is almost unbearable. The old code has given way in the field of its most enthusiastic devotees, about as badly as the Fugitive Slave Law did after the civil war had broken out. Yet the purest thing in this ark of the American Medical Association was the section about secret remedies and nostrums. We are pained to see unholy hands laid upon it, even in the name of Teutonic science."

Brown-Sequard Fluid in Tuberculosis.

The supplement to the *British Medical Journal*, January 10, 1891, says:

Dr. D. Uspenski, in a lecture recently delivered before the Russian Society of Public Hygiene (*Deutsche Medizinal-Zeitung*, December 29, 1890), gives an account of some clinical experments which he had made with Brown-Séquard's "emulsion" in the treatment of tuberculosis. He had tried this preparation in eighteen patients in different stages of the disease. Two of them had been quite given up. In one of these the patient was a lad of eighteen who had long suffered from mitral insufficiency, and who became the subject of acute phthisis in the beginning of May, 1890. After all other means of treatment had been tried in vain Uspenski had recourse to injections of Brown-Séquard's fluid. After the first three the general condition and the appetite were greatly improved, and after six injections the patient was able to leave his bed and walk about the room. The treatment was continued with the result that the strength and weight increased, while the temperature gradually fell, and the night-sweats diminished. After ten injections the latter ceased altogether, and the patient had so far recovered his strength as to be able to take a long walk in the open air. On June 15 the last injection (the fifteenth) was given, and the patient continued, through the summer, to improve in health and to gain weight (from 122½ lbs. to 148¼ lbs.). The tuberculous process in the lungs was at a standstill. In the other case the patient was a man, aged twenty-eight, who developed phthisis after influenza. There was considerable fever, with profuse night-sweats. There was infiltration of the right and, to a less extent, of the left apex, and tubercle bacilli were present in the sputum. At the beginning of May injections of Brown-Séquard's fluid were commenced; after the sixth the appetite increased, and after the twelfth the patient's condition was so much improved that he was able to leave his bed. After the eighteenth injection the temperature became normal. There has been no increase of weight, nor is there any perceptible amelioration in the condition of the lung. The patient, however, feels much better. In chronic cases the injections act more rapidly. In twelve such patients there was marked general improvement, with reduction of temperature and diminution of night-sweats after from two to four injections. Nine, or, at most twelve, injections usually suffice. Even amid the unfavorable surroundings of a prison infirmary Uspenski obtained good results by this treatment in seven cases. He considers that Brown-Séquard's fluid has a markedly strengthening effect, and is beneficial in all cases of phthisis without exception, whether the patients have any additional treatment or not, and whether they live under favorable conditions or the reverse. The tubercle bacilli do not disappear entirely, even in the most successful cases, but diminish in number in proportion to the extent to which the diseased process recedes. Uspenski says the remedy does not kill the bacilli, but weakens their pathogenic power.

Practical Method for Staining Tubercle Bacilli.

Assuming for the present that a practical process for staining and mounting tubercle bacilli will be acceptable to those of our readers who are already in possession of, and familiar with, a microscope, we will quote here a method of proceeding recently published by Dr. M. Friendlaender, of Berlin (in *Pharm. Zeit.*, November 22). This method permits two mountings to be made in from five to ten minutes, provided the operator is skilled and has everything in readiness.

The materials required are:

1. Ziehl's Solution.—This is a 5 per cent. aqueous solution of carbolic acid mixed with alcoholic solution of fuchsin (almost saturated).

2. A mixture of 100 gm. of alcohol of 80 per cent. and of 5 gm. of pure nitric acid.

3. A concentrated solution of methylene blue in water.

The mounting is done as follows:

A very small quantity of the sputum—about the size of the head of a pin—is taken up with the needle and spread by means of the latter upon an object-glass to a thin layer about covering the space of a ten-cent piece. The slide is then allowed to dry in the air, and meanwhile a second slide is commenced. The dry mounting is now drawn three times slowly through the flame of a Bunsen burner or alcohol lamp. Next 2 to 3 drops of the fuchsin solution are placed upon the mounting, and the slide held over the flame (mounting upward) until light vapors arise. The slide is now drawn once through water contained in a capsule, and the mounting then treated with a few drops of the acidulated alcohol, which is allowed to remain until the spot is completely decolorized (this will require about one-half minute). The slide is now again washed with water and then treated with a few drops of the methylene-blue solution, which is allowed to remain until the second slide (to which the operator now turns) has progressed to the same point. The first slide is now washed with water and finally dried with blotting paper [this is not advisable unless paper giving off no fibers is at hand] and over the flame.

Upon the mounting there is now placed a drop of oil of cedar (no cover glass), and the object examined with the lens (oil immersion objective).

Usually two specimens or slides suffice for determining the character of a sputum.—*American Druggist*, January 15, 1891.

Pleuritic Effusion in Children.

Dr. Herbert B. Whitney gives in the *Denver Medical Times*, December, 1890, an account of two cases of pleurisy with effusion in children, and then says: The treatment of pleuritic effusion should, I think, be very conservative. Without stopping to consider the measures, antiphlogisic and others, to be taken at the outset of acute febrile cases, I come at once to the important question as to whether paracentesis should be early resorted to, or should be as long as possible delayed. Henoch favors emphatically the latter course. He says the activity of tissue metamorphosis in children causes in general a more rapid absorption of serous exudations in them than in adults. He has seen so many cases of spontaneous absorption under simple diuretic and tonic remedies that he recognizes only two indications for operation: (1) When there is rapid and threatening increase in the quantity of fluid, so as to give rise to excessive dyspnœa; and (2) when the effusion has become purulent. In my two cases there was rapid absorption of the effusion under simple counter-irritation with iodine and tonics; in one, complete absorption in the unusually short space of a week, and in the second in about a month. I have also seen, in a child of three years, a pericardial effusion which was so large as to reach the sternal notch above and the nipple on the right, completely disappear under tonic treatment in the course of weeks. The number of cases also of empyema in children which recover fully after one or more aspirations, whereas in adults the radical operation is always necessary, is a further indication that the conditions in children are much more favorable for absorption than in adults. I believe, then, that paracentesis should be resorted to in those cases only where there is danger to life, or where long observation has shown no subsidence of the effusion under conservative and tonic treatment. An out-of-door life is usually indicated, and mountain or sea air is often very beneficial.

Early Spontaneous Rupture of the Uterus.

The *Lancet*, January 10, 1891, cites a case of rupture of the uterus, reported from Mexico by Dr. Eduardo F. Plá in the *Crónica Médico-Quirúrgica*, which is in several respects almost unique. The patient was a married woman twenty-one years old who had had only one pregnancy, which terminated satisfactorily five years before, since which time she had had no illness. A medical man was summoned hastily, as she had been suffering intense pain, and had suddenly become cold and collapsed. When he arrived she was dead. The official *post-mortem* examination was entrusted to Dr. Plá, who, after noting the absence of any marks of violence, opened the abdominal cavity, and found a quantity of blood and coagula, also the amnion containing a four months fetus, with umbilical cord and placenta. This had escaped by an irregular rent across the fundus of the uterus three inches in length. There were coagula in the cavity of the uterus, but no pus or

evidence of inflammation in the pelvic organs. The uterine wall was found to be extremely thin in the neighborhood of the rupture—under two millimeters—though in other parts it was as much as eighteen millimeters in thickness. A microscopical examination, which was made by Dr. San Martin, showed that in the region of the rupture the muscular coat was practically absent, being represented by a very few attenuated fibers; the mucous coat, too, was absent, being replaced by fibrous tissue without glands and with scarcely any vessels. Altogether the appearance was that of a cicatrix, but no history of any injury or disease could be obtained. The placenta was perfectly normal.

Charpentier mentions eight cases of uterine rupture at or before the end of the fourth month of pregnancy, and Dr. Plá mentions two cases cited by Burns in addition; these ten being all that he could find in literature. In most of these cases the patient was much older and had had difficult previous labors, and, again, the seat of the rupture was much less commonly the fundus than the lower segment. In the present case, being over the insertion of the placenta, the hemorrhage was great, and so led to the immediate fatal termination, whereas several of the other cases died later from peritonitis, and in one, that recorded by Dr. Drake, the fetus ultimately made its way out through an abscess in the umbilical region.

Anti-Kidnapping League.

The *Public Ledger*, of Philadelphia, states that the week before Christmas a new national association was organized in New York, under the name of the "Anti-Kidnapping League." The purpose of this league is to hunt down every case of imprisonment of sane persons in insane asylums which it can hear of, and give such assistance as the case demands.

The idea of the League originated with Miss Clarissa Caldwell Lothrop, of New York, who was herself the victim of the kidnapping the society has been organized to prevent. She was incarcerated for two years in an asylum, and when she was released she began the work of exposing the evils of which she knew, at the same time working for the organization of a national society to prevent the kidnapping and incarceration of sane persons. The society was organized December 19, 1890, and many men and women of position and influence are included in its membership.

It is said that the investigations of the League show that in seven years fifty-six sane persons were imprisoned in the Buffalo Asylum, and that this is admitted by the Asylum authorities in their reports. It is also asserted that the Utica Asylum admits that over one hundred sane persons have been imprisoned there in thirty years. The Society admits in many cases there is no fault on the part of the Asylum authorities, but says that the fact that eleven sane persons are annually incarcerated in two institutions shows that in the numerous public and private asylums there is a field for the Anti-Kidnapping League.

The Physiological Action of Sulphaldehyde.

Sulphaldehyde, produced by the action of sulphuretted hydrogen on ethylic aldehyde, occurs in the form of an oleaginous liquid of a repulsive odor, solidifying slightly below the freezing-point. Treated with acids, sulphaldehyde is transformed into a solid, the point of fusion of the various articles of commerce varying in accordance with their greater or less purity. Its analogy in composition to paraldehyde led Dr. Lusini to test the physiological action of the sulphaldehyde, administering it by injections intraperitoneally, and into the stomach of rabbits and frogs (*Les Nouveaux Remedès*, November 8, 1800).

It appears that sulphaldehyde produces profound and tranquil sleep without any phenomena of excitation. On account of its insolubility, some time is required before its effects follow its administration; nevertheless, it is claimed to be much more energetic than paraldehyde. It is eliminated completely by the urine, to which it gives its characteristic odor.—*Therapeutic Gazette*, January, 1891.

Cocoanut for Tape Worm.

Dr. W. R. Allison, of Good Hope, Ill., writes, in the *Peoria Medical Monthly*, November, 1890, of a man aged 35, who had always enjoyed good health, and who noticed some time ago that segments of worm were found in the discharges of the bowels.

He was ordered to fast for twenty-four hours and to take before breakfast the fol-

lowing day some pumpkin-seed tea, followed with a laxative, with the good results of causing the expulsion of about eighteen feet of the worm. All seemed well for about six weeks, when segments again appeared in the stools and were also discharged in his study or sleep. The man was accordingly given felix mass and passed about fifteen feet of tænia solium, which gave the usual result of seeming health for a period of from four to six weeks, he being able to sleep well and complained only at the time of the reappearance of the segments, of a slight inability of concentration of thought. He never seemed to have any other symptom of the parasite.

He now used chloroform and at another time turpentine with no good results when he by chance read of some one who had eaten a cocoanut and was surprised to see that he had discharged a tape worm. Accordingly he determined to try the same remedy, and was rewarded for his efforts by the discharge of twelve or fifteen feet of worm. As cocoanut is more pleasant to prescribe than many of the usual remedies, and does good with no bad results to the patient, and brings the worm without the usual following of a cathartic, Dr. Allison is pleased with its effects.

His patient drank the milk and ate the meat of the nut until he was satisfied that more would have made him sick.

Another Koch Institute in New York.

The daily papers of February 3, announce that a new Koch Institute for the treatment of consumptives was opened in New York the day before. It is a four-story brick structure, fitted up with all hospital conveniences. There is room for thirty-five patients in it. Dr. Alexander I. Aronson, who spent three months in the Berlin Clinics under Koch, is in charge and will be the resident physician.

[Now is the time to conjure consumptives by the name of Koch; before long it will be too late.]

New Operation for Club-Foot.

The Annals of Surgery, December, 1890, says that Dr. Mensel, of Gotha, has enucleated the bony nucleus in the neck of the astragalus of a patient suffering from congenital bilateral club-foot. The patient had had the regular orthopedic treatment for club-foot, but after forcible redressement of the feet, plaster and splint were applied, and after eight days the patient contracted gangrene from pressure on both feet. During the process of granulation the feet not only became as bad (varus) as originally, but even worse. The cicatricial tissue was not favorable to the treatment in the regular way, and the author exposed the astragalus of the patient (2½ years old). At this age the astragalus is composed for the most part (body) of cartilage and the bone nucleus is situated in the neck of the bone. It was comparatively easy to expose the neck of the bone without opening either the scaphoid or ankle joint, and by cutting into the neck the bony centre could be easily enucleated. The deformed bony nucleus may be very potent in the causation of the varus position, and after its removal the cartilage can be easily molded into a normal position. After removal of the above it was easy to bring the foot into good position without any great force, and cure was complete. The advantage gained is the retention of the body of the astragalus and the integrity of the ankle and scaphoid joints.

The operation is only indicated before the third year, and author would only perform it when the orthopedic treatment is not possible.

OBITUARY.

JOHN McCARRELL, M. D.

Dr. John McCarrell, who has for many years been a subscriber to the MEDICAL AND SURGICAL REPORTER, died at Wellsville, Ohio, January 18, 1891, about seventy years old. Dr McCarrell was born and reared in Washington county, Pa. He read medicine and practiced fifteen or twenty years, then about 1866 removed to Wellsville, and rapidly won a practice which proved very lucrative. He had not a very robust constitution, yet seldom saw serious illness. When dangerous disease did get a firm hold upon him it carried him off in brief period.

Dr. McCarrell was a man much loved and trusted in the community in which he lived, and an exemplary Christian. His life was one of usefulness and beneficence, and his death is deeply deplored.

Clinical Lecture.

CHRONIC ENLARGEMENT OF THE TONSILS OF CHILDREN.—EPILEPSY.[1]

BY H. A. HARE, M.. D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN IN THE UNIVERSITY OF PENNSYLVANIA.

Gentlemen: The first case I have to show you this morning is one of a character which is quite frequently met with, namely, an enlargement of the tonsils with some follicular inflammation, but chiefly consisting in an increase in the connective tissue, an interstitial tonsillitis of a chronic type. This condition is accompanied by a protrusion of the tonsils across the pharynx, in this case touching the uvula on one side, and almost touching it upon the other. Often the uvula is touched upon both sides. On examining this throat, you will notice that the mucous membrane over the tonsils is hyperemic, reddened and inflamed, but not covered with the white spots which are frequently seen. This tells us that this is not a case of pure follicular tonsillitis; for in it we have large quantities of a cheesy material poured out, which so closely resembles the false membrane of diphtheria, that a false diagnosis is often made. The exudate can be removed, however, on a small probe, and leaves behind it no bleeding or raw surface. This is not the case in diphtheria, where the membrane is adherent, and on removal leaves a bleeding surface. In acute tonsillitis, true quinsy, or suppurative tonsillitis, death seldom occurs. It is curious that strangulation does not more frequently occur from rupture of the abscess during sleep, or that pneumonia does not result from the swallowing or breathing in of this material, the so-called *Schluck-pneumonie* of the Germans.

Most commonly these cases come to the physician because the child has a constant paroxysmal cough, which almost ceases during the daytime, but is persistent at night, especially in the early hours of sleep. A careful examination of the chest in these cases of tonsillitis shows no sign of pulmonary trouble. The cough is a pharyngeal or uvular cough, due to irritation. The cause of the cough is not identical with that of an ordinary cough, but is due to the two enlarged tonsils which protrude and tickle the uvula. During the daytime the muscles are held tense, and the tonsils are thus prevented from touching the uvula; but if an involuntary relaxation occurs, as in sleep, the uvula is tickled, cough results, and the child awakens. At times it is even necessary for the child to sit up in bed to relieve the cough.

It is difficult to treat such cases; much more so than cases of acute follicular tonsillitis, which may be treated with diuretics and cardiac sedatives, and with the local application of cold or heat. In the treatment of the present variety, several interesting points must be considered. Is chronic interstitial fibrous enlargement of the tonsils severe enough to interfere so seriously with respiration as to make the removal of the tonsils necessary? A great many physicians, especially in France, recommend their removal. On the other hand, I have seen several experienced surgeons operate upon the tonsils and encounter excessive hemorrhage. As you well know, any severe operation upon the mouth is very apt to be accompanied by profuse hemorrhage.

The next heroic treatment after tonsillotomy is igni-puncture, or the use of the actual cautery. It consists in the insertion into the enlarged mass of a small electric cautery, or the ordinary red-hot iron. The inflammation which ensues around the burns

[1] Delivered at the University Hospital.

results in fibrous or cicatricial contraction, with a consequent decrease in size of the organ. This results in a ragged-looking tonsil, with crypts in which food may accumulate and undergo decomposition, with the production of fetid breath. A mouth wash or gargle of carbolic acid (1 to 100), sweetens the breath and prevents decomposition from going on. Notwithstanding its drawbacks, however, igni-puncture is the operation to be resorted to, instead of tonsillotomy. It is safer and just as efficacious. However, in all these cases, the patient at first desires you to temporize with medicinal measures; and probably the best medicine for an adult is iodide of potassium, five grains three times a day, at the same time painting the tonsils with equal parts of iodine and glycerine, or one part of iodine to three parts of glycerine, and also painting the skin externally with tincture of iodine, or rubbing in iodine ointment. If you employ iodine ointment over enlarged glands in children, it must be mixed with lard; as it is too strong to be applied in its officinal strength. Simple or benzoated lard may be used with an equal amount of the iodine ointment. If the child is the age of this one (8 years), probably you will not be able to give it iodide of potassium in effective doses, as the drug would be apt to disorder the stomach. You should use in its place the syrup of the iodide of iron internally. Most of these children are anemic, and iron is needed. Iodide of iron also exerts a peculiar influence over inflammation of the upper air passages. The syrup should be given in doses of five drops or more three times a day.

On looking at this child's tongue you will notice that it is black. This is due to the iron, which also blackens the feces. The discoloration is due to the presence of sulphide of iron. It is well to warn the mother that this will occur, to prevent needless alarm.

To be more definite, what shall we do for this case? We shall give her five drops of the syrup of the iodide of iron three times a day, and apply externally over the enlarged tonsils ichthyol ointment, night and morning, two drachms to the ounce of lard. If no irritation of the skin is produced, we shall apply it at noon as well. It is impossible to make applications to the tonsils internally every day, and it is dangerous to give iodine solution to parents of young children, with which to paint the child's throat. If I should give anything, it would be a solution of one drachm of tannic acid to two ounces of glycerine, to be applied with a camel's-hair brush.

I forgot to mention one other course of treatment which may be resorted to after igni-puncture, and that is the use of the solid stick of silver nitrate. This is especially useful when there is a complication of chronic interstitial tonsillitis with follicular tonsillitis. By using the stick in these cases you mildly cauterize the tonsils, and achieve good results.

The slight deafness which is frequently complained of by patients with enlarged tonsils is due to an extension of the inflammation from the tonsils to the Eustachian tubes, which either become patulous or plugged with mucus.

Epilepsy.

The next case is one of epilepsy: an extremely common disease, and of frequent occurrence among children. The case is one of ordinary idiopathic epilepsy, unfortunately not dependent upon trauma or tubercular growths, and consequently unfavorable as regards prognosis. It depends upon some organic change which the microscope so far has not been able to reveal. The boy, however, has one symptom which gives us a clue, sufficient to start us on a tour of investigation as to whether it is a true epilepsy, or an epilepsy hysterical in origin. His aura consists in the sensation of a globe rising in the throat, which, as it reaches the level of the glottis, terminates in an attack of epilepsy. Hysterical epilepsy may occur in young males as well as in females. There is also a possibility of this case being one of the so-called reflex epilepsies. A number of authorities claim that there is no such thing as a reflex epilepsy; but I think that it is proved conclusively that a certain number of these cases are reflex, and in such cases the removal of the cause is apt to be followed by a cure of the epilepsy. An adherent and elongated prepuce is one of the most common causes of this variety of the disease. In such cases the prepuce is never thoroughly emptied of urine; and the retained urine sets up an inflammation which may even result in ulceration. In other cases a large amount of smegma collects around the corona, and an inflammation is thus excited. In these cases circumcision is always to be tried. It may or may not do

good. In other cases some foreign body may be found in some portion of the system, which by its presence creates sufficient irritation to produce a reflex epilepsy. The nose especially should be searched for such a cause, as beans and other bodies are often placed there by children.

The variety of the auras which come on in epilepsy is very great. Probably there are as many as ninety different forms described. The globus hystericus, tingling in the fingers, tingling in the toes, hallucinations and sudden interruption of the heart, are but a few examples of the great variety of forms it assumes. There is a point of interest in regard to treatment connected with the aura. If an attack is always preceded by an aura, the prognosis is more favorable than if the aura does not come on. One nervous act always predisposes to another nervous act, and the second act is much more violent as a rule than the first. This is especially noticeable in epilepsy. Now you can see at once that those cases which have an aura may be more favorable in prognosis than the others; since, if the aura is of any duration we can generally, by using nitrite of amyl, avert the subsequent nervous act; and if we do not have the first nervous act, we will not have the second. Thus, if the patient can succeed in putting off his attacks for a year, he will probably be permanently improved. For this purpose, pearls of nitrite of amyl, containing two or three minims each, should be kept in the pocket, and one should be broken and used from a handkerchief as the aura is felt.

Another factor governing the prognosis of these cases is to be found in the habits of the parents as regards the use of alcohol. A number of statistics made in France show that a child of alcoholic parents is especially liable to epilepsy; and this is greater if both parents are addicted to the use of alcohol. The prognosis is more grave when both are alcoholics. Syphilis also must never be overlooked in these cases.

In a certain number of cases of epilepsy it will be noticed that the child will have a rotatory convulsion preceding the attack. What the cause of these rotatory convulsions is, is not fully known.

This boy does not suffer with prolonged unconsciousness or coma, as is usual in most cases.

There is one other thing I should impress upon you in studying a case of epilepsy. Ascertain if any portion of the body is first affected, as evinced by a movement of one thumb, or of a hand, or leg, or by a flushing of one portion of the body. This may give a clue as to where the lesion is that produces the attack, or indicate whether or not the disease is idiopathic in nature. I remember seeing a man under the care of Dr. Hughlings Jackson some years ago, who was paralyzed in the lower extremities from Pott's disease, and who suddenly developed an epilepsy in which the movements were confined to the upper extremities. The thumb of the right hand was the first portion of the body affected by the paroxysms, and the diagnosis was made that the thumb centre upon the opposite side of the brain was involved. Accordingly the man's skull was trephined, and a tumor the size of a hickory nut was found and removed, with subsequent complete or partial cure of the epilepsy.

In the treatment of these cases of epilepsy, bromide of potassium is the standard remedy. I think that sodium bromide is better for children, as it is not so apt to disturb the stomach. The best way to administer it, is in solution; since it deliquesces if in powder form. Some authorities claim that it is not so active as the potassium salt; but I am unable to vouch for the accuracy of this assertion. In gouty cases, the bromide of lithium may be of service. In all cases endeavor to put off the attack by the use of the nitrite of amyl. If you give bromide of potassium to a child—and always when you are giving it to women—give with it Fowler's solution. This exerts a useful influence on the disease in some cases, and it also prevents the formation of acne. Two to three drops should be given with ten grains of bromide.

A form of reflex epilepsy which I should have mentioned, occurs in little girls from the migration of seat worms from the rectum into the vagina, with the production of great reflex irritation and convulsions. The cure of the disease here is obtained by removing the worms. In all cases of this kind, however, the prognosis must be guarded. If the child has had but one or two fits, the prognosis is good; but if it has had ten or twelve, the habit has been produced, and this may become more and more persistent as the child grows older.

—Helenin, the active principle of elecampane root, is claimed by Marpmann to prevent development of tuberculosis.

COMMUNICATIONS.

CLIMATIC TREATMENT OF PHTHISIS.[1]

BY J. P. CROZER GRIFFITH, M. D.,

PROFESSOR OF CLINICAL MEDICINE IN THE PHILADELPHIA POLYCLINIC; PHYSICIAN TO ST. AGNES AND THE HOWARD HOSPITALS, AND TO THE RUSH HOSPITAL FOR CONSUMPTIVES.

That change of climate is one of the best—and sometimes the only—means of successfully treating phthisis is so universally admitted that it seems almost unnecessary to make mention of it. There are, nevertheless, certain details regarding it, which it may be not without interest to pass in review. For centuries this method has been in repute. The Romans used to send persons with ulcerated lungs to Libra that they might there inhale the balsamic odors from the pines; and Galen advised that phthisical patients be sent to localities in which the air was dry.

Even those who write upon the Home Treatment of consumption, admit the value of climatic treatment where it can be carried out. It goes of course without saying that the vast majority of phthisical patients, owing to pecuniary or other disability, cannot be sent away from home. The all-important subject of the means to be employed for the recovery of health in these, I cannot now treat, but must confine myself strictly to the subject of the influence of climate upon the disease.

I am myself so thoroughly convinced of the value of climato-therapy in phthisis, that were I assured that I had incipient phthisis, however slight, neither inhalations of oxygen, nor the use of compressed or rarified air, nor the breathing of hot air, nor enemata of foul air, nor trial of Koch's inoculations, nor pulmonary gymnastics, nor the ingestion of cod-liver oil, iron, arsenic, digitalis, creasote or any other drug should prevent me—if in any way I could compass it—from leaving a climate such as this for some more propitious one. And yet there are the sceptical—there always are, of every good thing. Let me, however, give you as samples, the histories in brief of two cases which were sent to parts of the world far removed from here and from each other:—the Austrian Tyrol and Colorado. They occur to me because I have heard from each of them within a short time. The first patient developed apical phthisis some five or six years ago. Being a man of means he traveled, chiefly to various parts of the eastern United States, remaining in each place but a short time and returning again home. While away he improved, but always lost again on coming back. Finally his cough grew worse, there was slight hemoptysis, and examination showed decided depressions at the left apex with dulness on percussion, bronchial breathing and râles. I sent him to Meran in the Austrian Tyrol, where he remained for over a year. On his return I was astonished to discover that the dulness on percussion, the depression and bronchial breathing had entirely disappeared; leaving nothing but a few râles. An improvement such as this had not been effected by all the medicinal and hygienic treatment to which he had been previously subjected. I told him, however, that he had returned too soon, and the event proved the truth of this. He was shortly after returning, debilitated by a very severe attack of herpes zoster, and the subjective and objective symptoms of the phthisical affection returned in full force by the end of a year. He has again gone to Meran, where he now is, and is doing remarkably well. He has no cough at all, and only slight expectoration on rising in the morning. Can he be induced to remain sufficiently long, I have no doubt of his complete recovery.

The other patient is himself a physician from a neighboring city. He called upon me last July on account of obstinate cough, with loss of weight and strength, which drugs, rest and a temporary mountain sojourn had failed to relieve. He suspected phthisis, and wished to have a diagnosis made. Neither bronchial breathing nor impairment of percussion resonance could be detected, but there were a large number of râles at the left apex, and a few on the other side. Tubercle bacilli were present in the sputum. I told him there was no doubt he had incipient phthisis, and advised him by all means to go to Colorado and begin the practice of his profession there as soon as he felt able. He did so, and wrote me the other day, saying that he had gained 22 lbs., but asked my advice about coming on to take the Koch treatment, as he did not believe that he was yet quite cured. My

[1] Read before the Philadelphia County Medical Society, January 28, 1891.

answer can be readily imagined. But cases like these are known in numbers to all of you. Only recently one of the members of this Society told me that, visiting in Denver recently, he sat down to dinner with, I think, fifty men, all of them as hale and hearty as one could wish to see, though all or nearly all of them had gone West on account of trouble with the lungs.

Now as to the way in which climate can act in curing phthisis. If it is the fact, as most of us certainly firmly believe, that phthisis is the direct result of the growth of the tubercle bacilli in the lungs, the question naturally arises how climate can in any way affect the growth of these organisms after they have once found a nidus in the system. This question cannot be answered with positiveness. One matter bearing upon it is, however, nearly certain. It would seem probable that the only reason that all of us do not take the disease is that, either from the good condition of the general health, or from some peculiar, unsuitable state of the respiratory tract, the bacilli which we all probably inhale at times, do not find in certain individuals the conditions suited for their development. Given, then, a patient with pulmonary phthisis, our efforts must be to render the lungs again of such a quality that bacilli already present can no longer thrive and multiply. It seems beyond question that certain climates have the power of accomplishing this desideratum in some way unknown to us, but certainly more effectively than any other known agent. What peculiar climatic features they are which have this power is, as yet, not determined with definiteness. The most generally accepted view is that high altitudes, as a rule, are inimical to the development of phthisis, and conducive to the recovery of those already affected; while a low elevation above tide-water, especially if combined with dampness, continued high temperature, or frequent changes of temperature, favors its development. Particularly are writers almost at one in reference to the favorable action of high altitudes. Phthisis is of rare occurrence, for example, in the high mountain cities of Mexico, in spite of the unfavorable influence exercised by the bad hygiene and the employment of the inhabitants largely in mines.

The disease is almost unknown in the high plateaus of South America, and rare in the high portion of the western United States. Switzerland is, on the whole, remarkably free from it, and it is very rare in the highlands of upper Egypt. In the western Highlands of Scotland, too, it is uncommon as compared with other parts of the British Isles.

It is not yet definitely understood whether the immunity of the dwellers in high altitudes is due to the low barometric pressure or to the purity of the air. The view has not found favor that it is in any way connected with the greater depth of the respiratory act; nor does the statement that microbes live with greater difficulty at a high elevation satisfactorily explain it. That the influence of high elevation is not due, at least entirely, to the low barometric pressure seems probable; since, as is well known, prolonged sea voyages are often of great benefit to phthisical patients. Moreover, some islands, as Iceland and the Hebrides and Shetland Islands, are singularly free from the disease; and the Kirghis enjoy an absolute immunity, although they inhabit steppes only 100 feet above sea level,

It has been long assumed that odors of turpentine and allied substances coming from pine forests were of value in the treatment of phthisis, and it has been claimed that to this factor sojourn in the Adirondacks owes the undoubted advantages often exercised by it in many cases of phthisis. There are clearly, however, other important factors; since otherwise all regions filled with these woods should exert the same favorable influence. Yet there are many such districts—as Maine—where the mortality from phthisis is high. One might argue that the mortality in such places was the result of too great a degree of dampness; but in answer it may be noted that many islands, as already stated, where the air is, to an extent, damp, suffer but little, if at all, from phthisis. In fact, the prevalence of the disease does not seem to be connected with any geographical position or condition of temperature.

Our knowledge in this regard may be summed up by saying that change of climate is very often of the greatest benefit to phthisical patients, and that, as a rule, this benefit seems to be intimately associated with elevation above tide-water, though there are many localities with no considerable altitude where a good effect is often exerted upon the disease.

It will repeatedly be observed that the relation of a patient to a certain climate is very much like that which exists, or should exist, between a man and his wife. Just as

one man finds in his wife's character and disposition that which entirely satisfies his moral nature, while his neighbors, perhaps, can see no good in her at all; so one phthisical patient may thrive in a certain locality, while the next patient, with lungs in apparently the same condition, is never comfortable there, and suffers a continual deterioration in health.

It is this fact which renders the matter of choice of climate so exceedingly difficult. It is impossible entirely to determine the nature of what might be called *climatic idiosyncrasies* in patients. We are, therefore, obliged, in the choice of a climate for a patient, to follow certain general rules. First is to be investigated the individual susceptibility to cold and heat respectively. We must carefully inquire whether the patient is always chilly in winter, or whether he is exhausted and depressed in summer. It seems to me to be folly as well as cruelty to compel an anemic, emaciated individual, who is always chilly and whose circulation is feeble at the best of times, to spend a winter in a cold, bleak, windy, northern elevation. While the Adirondacks in winter are certainly of benefit to many, it would seem almost proved that they cannot but disagree with others; in fact, experience proves that they do. On the other hand, there are many patients to whom even the early spring warmth of Florida is invariably depressing, and who reap no benefit from sojourning there. It is, after all, hygiene throughout which we must keep in mind, and not merely the effect of a certain climate upon the lung alone, as though it did not belong to the body.

Another factor of some importance in selecting a locality is a knowledge of the *diurnal* range of temperature. The annual average temperature, and the average for each month, can usually be ascertained without difficulty for the more frequented health resorts, but the daily variation is not so easily to be learned; and yet it is on just this factor that the comfort of the patient may depend. A perfectly equable temperature is certainly of great advantage. Unfortunately it is not so apt to be found with dry air and elevation above the sea as it is at lower regions. Although elevation is, as a rule, much the most important, yet in some cases it will appear best to select the sea on account of the smaller diurnal temperature range.

Still another matter is the nature of hotel accomodations and other creature comforts; and this has to be considered most carefully in reference to the individual. Though a strong man with beginning phthisis, which has had but little effect upon his general health, may do well if sent to a region where he will spend his days in the saddle and his nights in the open air; it is clear that, for women and many male patients, no such regimen can be prescribed.

Patients want to know all these and similar details before leaving home, and it is well if the physician can help them in this respect. In many cases, however, circumstances prevent more than the pointing out of a general plan of action; especially as the number of places recommended as health resorts in phthisis is so large.

Individuals, with beginning phthisis, who are unwilling to make a radical change, or in whose case the physician does not deem it expedient, might seek Florida in winter, returning northward in the spring by slow stages, stopping *en route* in Georgia and North Carolina. In the summer some mountain resort should be selected, preferably the Adirondacks. There are, nevertheless, weighty objections against this course. It is very difficult to return North without feeling the bad effect of the change of temperature; while a still greater objection is that the length of time, during which this continuation of travel must be persisted in, is too great for the patience of the invalid, thus kept so near home and occupation, and yet debarred from them. I have, however, seen cases, presumably of phthisis in its earliest stages, apparently entirely cured by a short absence from home in some such manner as this. It might be well in some instances to begin treatment in this way; but if the physical signs are well marked, only the shortest trial should be given to this plan, as valuable time may be lost thereby. These more advanced cases, if in fairly good condition, and offering good hope of final recovery, should at once be subjected to a radical change of climate—either for an indefinite period, or for life.

The question whether a station in the mountains or at the sea level is to be selected must be decided to some extent in accordance with the idiosyncrasy of the patient, as far as this can be determined in advance. As a rule, a mountain resort is far preferable and should be chosen whenever practicable. Statistics certainly show that the results in the mountains are better.

Our own country offers several excellent localities for phthisical patients. Of all of them perhaps the high altitudes of Colorado are to be preferred, since here can be found comfortable accommodations combined with pure, dry air and high elevation. In the "Parks" of this State we find table-lands of 10,000 feet elevation above the sea, protected by surrounding mountain peaks, and with an annual range of temperature less than in the Eastern States of the same latitude. Sudden diurnal changes do occur, it is true, but to no greater extent than in all elevated regions. The rainfall is, also, very slight. It has been stated that the dust prevalent as a result of this is irritating to the respiratory tract; but this is denied by those who have accurate knowledge in the matter. In spite of the thousands of phthisical patients who frequent the State the death-rate from consumption is very low.

New Mexico and Arizona offer somewhat similar advantages in the way of climate; but the facilities for living are not so great. The summers, too, are apt to be very hot. There are localities in Texas, too, which are excellent.

Southern California presents many advantages, not the least of which is that patients can easily vary their elevation from that of the sea level to a considerable mountain height, according to the different seasons of the year, and to what is found to best suit their health.

Florida is not so favorite a resort as formerly, and physicians preferring high altitude will not, of course, recommend it at all.

Phthisical patients in Europe can make choice from a large number of summer stations, all equally good, or can go from one to the other as fancy dictates. A winter one may be chosen in like manner. The passage from one to the other may be made gradually by means of intermediate stations whose climate is midway between that of the others.

Nowhere does the climatic idiosyncrasy come into play more than in the choice of quarters in Europe; what suits one patient for winter, for example, being entirely too rigorous for another. For summer time there is, as a rule, probably no better place than the high valleys of Switzerland, and prominent among these is the Engadine valley. This valley, however, is scarcely free from snow before the middle of June or the first of July, and becomes cold early in the fall; so that, as a pure summer resort, it is not long tenable. It is also subject in summer to cold and disagreeable winds. In spite of this it is unexcelled by other localities for the climatic treatment of phthisis. Davos-Platz also enjoys a similarly good reputation. The neighborhood of Zermatt also fills the requirements of elevation and coolness during the hotter summer months. There is no difficulty in choosing among a number of other places equally well adapted. Lower valleys may be selected if the summer is unusually cool, but the higher elevations are much to be preferred, as far as freedom from phthisis is concerned. Farther east there are various resorts in the Dolomite region which are highly recommended. There are numerous other places throughout the mountains of Germany, but for American patients Switzerland and the Tyrol offer every advantage to be derived from climate, while they possess other desiderata not to be found elsewhere.

For early summer and early fall other localities than those mentioned are to be preferred. The choice of such a station is a rather more difficult matter. Some of the lower portions of Switzerland may be selected; as Interlaken, the neighborhood of Lucerne, and the shores of Lake Geneva. Probably the latter situation is the best. Vevey and Montreux form here excellent intermediary stations. Ischl and Reichenhall, in Austria, are also recommended, and the Black Forest, in Germany, presents many attractions. One station which offers in some respects peculiar advantages as an intermediary station is Meran, in the Austrian Tyrol. It is beautifully situated and sheltered from the winds; and patients are able to spend a great deal of the time in the open air.

Finally, as to the choice of a winter station. For weakly individuals who shun any degree of cold or variation of temperature it may not seem best to select an elevated station. For such the south of France, the south of Italy, Sicily or the Riviera, have long and justly been popular. Or the patients may pass from Europe into Egypt, Algiers or Morocco. But for uniformity of temperature and of barometric pressure there is probably no place known equal to the Canary Islands. Madeira, once so popular, has fallen off greatly in general favor. For a large number of phthisical persons a dryer, colder and more bracing climate at a greater elevation is more suitable, even in winter. For these Meran is eminently

adapted, provided only a moderate degree of cold is desirable. The sunshine here is always quite warm, and patients are able to sit out of doors in it the greater part of the day.

Still more popular have the Engadine valley and Davos-Platz become, even as winter stations. The cold, it is true, is severe, but it is dry cold, and the unpleasant, raw winds of summer are absent at this period of the year; while the thermometer in the sunshine registers high, as is usual in all climates of high altitude.

It is to be borne in mind as an inviolable rule, that such a climate is to be selected either for summer or winter, as will allow the greatest amount of exercise in the open air with the least discomfort to the patient, and with the greatest advantage to the general health.

What has been said is but the briefest and a necessarily incomplete outline for governing the choice of climate for the patient. A few words must be added on what might be called the choice of the patient for the climate.

There has existed a wide-spread prejudice against high altitudes in cases of decided tendency to hemoptysis. This prejudice is, in the opinion of the best authorities, unwarrantable. Patients with this tendency are perhaps even safer in the mountains than at the sea level. The cases most suited for climatic treatment of any kind—as, indeed, for any other method—are those with but slight infiltration, with but few symptoms of the disease, and with strength sufficient to permit of abundant exercise. These patients should, as a rule, be sent to high altitudes for summer, and very probably for winter also. Other cases with a greater extent of pulmonary lesion, and with a less degree of strength or of resistance to cold will probably need the lower, warmer winter resorts, followed by the intermediary stations, and these again by the highest elevations for the summer months. In a still more advanced stage of the disease, especially where there is much elevation of temperature with severe subjective symptoms, the patient is not in a condition to stand much traveling nor to take much exercise. In such cases cold situations are out of the question. A warm, equable climate is to be chosen, and the nearer home the better. If improvement take place a more mountainous locality should be sought as soon as possible. The existence of fever is not, however, *per se* a contra-indication to high altitudes. It has often been observed that patients lose all fever soon after reaching the mountain resorts. Nor is the presence of a cavity a contra-indication in the selection of high elevations, provided the lung is not evidently rapidly breaking down. Cases which are very far advanced and evidently hopeless should not, of course, be sent away at all; for only a hastening of the final end of the disease can come to the patient, with disappointment to the family, and reproach to the physician. It should be further clearly explained to patients, in whatever stage the disease is, that change of climate is not an infallible cure, and, further, that with it must be conjoined all other necessary hygienic and dietetic measures, together with the employment of such medicinal agents as are indicated by the disease.

PERMANENT OPENING OF THE DRUMHEAD AND THE ARTIFICIAL DRUMHEAD.

BY B. M. BEHRENS, M. D.,

CHICAGO, ILL.

It is the common belief that perforation of the drumhead is a final result of an otitis media, or tympanitis, and that the closing of the perforation is well-nigh impossible in most cases. This sceptic view is held not only by the medical profession at large, but also by otologists. Of this we can convince ourselves best in the otological text-books, where it certainly is mentioned, that the

perforated drumhead shows a vigorous effort at closing, or trying to close, but not a sufficently vigorous one. The last resource is therefore the artificial drumhead, from the little cotton pellet to the rubber drum, that may in some cases bring a naturul closure about by the continual irritating effect on the edges of the remaining part of the drumhead, but mostly is employed only with the view of improving the hearing and protecting the middle ear. It does improve the hearing very often, of course; but the protection of the middle ear is of so dubious a nature, that where it is possible to do better, it ought to be discountenanced. Where the perforation is of a large extent, the risks are less than in cases of small perforations, because we in the first cases can better master the ill effects that might be caused by the irritation of an artificial drumhead, but here also it is unquestionably the best policy to try to effect a closing of the perforation.

To dispel the existing scepticism, I have the pleasure of presenting some illustrations of cases that will explain the possibility of closing even large perforations better than words can do. Such cases are few and far between, for the reason that patients will seldom submit to a treatment lasting for months, not to speak of the uncertainty of the final result of the undertaking. In the course of several years, though, I have had so many good results, that I dare lay down the rule, from which there are very few exceptions, that any perforation of any size in the membrane proper can be made to heal up, provided the remaining part of the drumhead is not degenerated. I beg to remark that I speak of perforation in the membrane proper, and not of peripheral loss or defect, nor of perforations in the Schrapnell membrane. The secret of this rests in the fact that the drum membrane owes its great regenerative power to the elastic tissue in the membrane proper, while the Schrapnell membrane is entirely devoid of this tissue.

As to peripheral loss or defect, the difficulty of healing depends upon the fact that the bony part of the tympanic ring contributes a part of the aperture in the passage. Any effort to bring a natural closure about here is without avail, and the only resort for improving the hearing and protecting the middle ear is the artificial drumhead. The majority of perforations, though, are the concentric or excentric ones, either single or double, or more numerous—and the more, and consequently the smaller, the more tractable they are. As the supreme question always will be, whether the hearing will be benefited by a closure, the artificial drumhead is applied as a test. For this purpose it is sufficient to apply a small cotton pellet in the opening, or—what is better still—a small piece of sticking plaster over the opening in the membrane. If by this the hearing is improved, there is no doubt about the benefit to be derived from a natural closing, but if the hearing is not improved we are not so certain of the reverse. Politzer, and many other authorities have laid down this rule. It must be taken with some allowance, as the result must depend on other circumstances, as, for instance, the duration of the existing opening and the possible changes in the middle ear. So also as to the question of seeking a closing where the artificial drumhead produces noises in the ear. It is very well for a text-book, but only there.

There is so much difference between an artificial drumhead and a natural closure, that results obtained by the first are not to be compared with those obtained by a natural closure, because only under this can the tympanic cavity with its mucous lining and chain of ossicles return to the same condition it had before the primary lesion took place. The artificial drumhead is a foreign body, whose irritating and pressing effect is too predominating to give us any correct idea as to the final effect of a closing. It is not out of place either to assume that a direct treatment of the tympanic cavity through the opening will and can do much good, while the closing goes on, if proper remedies are employed. If ill effects are obtained after the closing, as, for instance, impairment of hearing and noises that were formerly not present, the after-treatment will have to be directed through the Eustachian tube, with injection of proper medicines, or resort can be had to surgical interference to bring about a permanent opening again. In cicatricial tissue this is not a very hard task. But I must say right here that it is not likely that we will have to resort to these things if the first testing with closing the opening is carefully made. For this purpose I must recommend the sticking plaster again, as being more reliable than the cotton pellet, or what is generally understood by the artificial drumhead.

If a considerable improvement of the

hearing be produced by covering the entire opening with sticking plaster, my proceeding is as follows. The whole ear is first thoroughly cleansed with a Listerine solution, and dried with borated cotton. After this I apply a 5 or 10 per cent. solution of cocaine, and let it remain in the ear for some minutes, after which I apply the borated cotton again to dry up the whole meatus. Next I put a cotton plug, corresponding to the size of the opening, inside of this, to protect the inner wall of the tympanic cavity, and apply the galvano-cautery burner to the inner edge of the opening, only slightly, so as to cause a superficial eschar. This done, I remove the cotton plug and apply another soaked in glycerine and dusted with iodoform powder, on the opening. Outside of this I apply a piece of oiled silk, and cover the whole with borated cotton to make it all air-tight and, so far as possible, aseptic. By this packing, the membrane is continually kept in a warm, moist condition, which is of paramount importance, if we want a rapid healing to take place. This proceeding is repeated once a week until the opening is closed. Sometimes it is well to stop for a while and then take the treatment up again.

In some cases I have tried chloride of zinc and argentum nitricum, but the best and quickest results I have obtained with the galvano-cautery. Of course, it is to be used with care, so as not to produce a larger opening, and it must, therefore, not be applied again until reaction has ceased. If, by these means, closure cannot be obtained, then we must look for hindrances elsewhere. It is quite frequent that the manubrium mallei is drawn inwards on account of the weaker resistance of the perforated drumhead, or there is somewhere adhesion between the edge of the opening and the inner wall. In the first case, I divide the tensor tympani, so as to bring about relaxation of the drumhead, and in the other case I separate the adhesion and apply a piece of iodoformed cotton, to prevent renewed adhesion. It might be inferred that this procedure is not without its risks. I can only say that I have never met with any unpleasant effects from it, although I have practiced it for many years.

My excuse for bringing this view of mine to the notice of the profession must be sought for in the fact that what I regard as an easy affair, is generally considered by the medical profession as unobtainable. As a rule, an old perforation of the drumhead is considered a final condition, and, therefore, it is left to the patient to find out for himself whether an artificial drumhead gives him any benefit or not. It may be that the patient falls an easy prey to the vendor of rubber drums, but the medical profession cannot regard this as a final victory. If the artificial drumhead would compare, for instance, with the correcting glass for a disturbed vision, it might rightly be suggested to let well enough alone; but there is no comparison, as the artificial drumhead sometimes endangers life, which the glass does not. Very often an acute otitis media sets in, produced by applying a soiled drumhead to such a delicate part as the tympanic cavity. Patients who are compelled to wear it for the sake of improving their hearing, may be ever so scrupulous in cleanliness, it cannot help but that some harm may be effected, because it concerns a locality which is not open to investigation and self-control, and we know for a certainty that it is never aseptic. Ignorance is bliss here, and has its analogy in the utter carelessness that is manifested by the laity in using the ear as a receptacle for almost anything with which to relieve an earache or the like. Resorting to the artificial drumhead as the *ultimum refugium*, puts a stop to further investigation as to altered conditions of the ear, brought about either contemporary with or after the primary lesion took place. By trying to close the perforation, we may probably do more good than the artificial drumhead can ever accomplish.

Last, but not least, there are a large number of our patients who, for the reason above mentioned, cannot and ought not use the artificial drumhead at all. I mean, children. To them it is an annoyance more than a benefit, and is, therefore, not much appreciated. The above mentioned lack of control makes the use of it especially dangerous in children, not only from their carelessness, but also from the weaker resistance to irritation in the tissues of a child's ear.

To prevent any misunderstandings, allow me to say that only perforations as sequelæ to an inflammation in the membrane proper, or in the tympanic cavity, are thought of, and not deeper or more serious lesions with destruction of the hearing bones, in which closing the aperture would only protect the middle ear, and would rather impair than improve the hearing.

CORYZA.[1]

BY G. P. SARGENT, M. D.,
BRYN MAWR, PA.

Coryza is perhaps the most common affection from which we suffer, and the disorder itself and its accompanying ills are so distressing at times as to call for preventive and remedial treatment. It is an acute inflammation of the nasal mucous membrane, and is held by some to be synonymous with nasal catarrh; but I look upon catarrh as a more deeply seated disorder or at least an advanced stage of this "cold in the head"—this nasal blenorrhœa.

It is commonly caused by a check of perspiration, or when there is no perspiration it is often induced by a current of cold air—not infrequently by inhaling cold air, as when one faces a sharp cold wind while driving. Cold feet and hands give rise to it at times, and a writer, in a well-digested article in *Chambers' Journal*, some time since, attributed many cases to a nervous disturbance. His paper was entitled: "The Nervous Origin of Colds," and in it he enlarged upon the fact that local irritation of nerves at the seat of the trouble or situated at a distance and acting by reflex influence, often produced coryza; and also upon the fact that it followed emotional excitement in some persons. Irritating vapors and dust frequently provoke an attack. A strumous constitution is especially susceptible; and there may be in some a hereditary predisposition. It is often present in measles and shows itself perhaps in its most formidable character in influenza. It may be epidemic; though it is not considered contagious.

The onset of the disorder is usually characterized by a sense of dryness of the nostril, with tickling and a great propensity to sneeze. The temperature of the mucous surface is reduced, to be subsequently elevated above the normal standard. The dryness and tickling are soon followed by a full flow of mucus. The engorgement is rapidly increased, and serum exudes, gradually becoming thick by the breaking down of epithelial cells and lymph corpuscles. There is a fulness of the head and dull and oppressive pain along the frontal sinus. The nerves of the region most affected being numerous and highly sensitive, the irritation, itching, sneezing and general discomfort become at times almost unbearable. In severe cases the eyes become suffused, the tear ducts are occluded, and smell and hearing are much impaired. In yet severer cases, as in hay-fever and influenza, the eyes become swollen and the skin of the upper lip and around the nose and eyes even sore from the irritation of the mucous discharge.

This is a most uncomfortable state of things, and one who suffers a severe attack is in a pitiable condition. Happily the disorder passes away in most instances in a few days, even without treatment, and thousands of patients pass through the several stages without check and without medical advice.

But, unfortunately, many apparent recoveries are only partial, and the inflammation is revived by a slight provocation, establishing a chronic catarrh, which every one knows is an obstinate, persistent and deplorable evil, interfering seriously with the entrance of pure air, and leading to debility, and either directly or indirectly to disease of various organs, and greatly vitiating the general tone of the system.

It is especially in hope of averting so serious a disorder as chronic catarrh that coryza should be treated at an early stage; since one who has suffered an attack and allowed it to take its course is more liable to suffer again, and by frequent visitations becomes debilitated and a prey to other forms of disease. For how can the blood be properly aerated if the breathing be interfered with?

We are not often called upon to give advice in cases of simple colds, the popular belief being that there is no way of cutting short an attack, and that it must have its course of a week or ten days. There are, however, remedies which, if employed early, relieve in a night eight cases out of ten. Dr. Ferrier, of London, devised a snuff composed as follows:

℞ Bismuth subnitrat. . . . . ℥ vi
Morphinæ hydrochloratis . . . . . gr. ii
Gum. acaciæ . . . . . ℈ ii

This is mixed and reduced to a fine powder, and one-fourth is used in a day.

I think it would be improved if the acacia were left out. It might be further improved by adding a grain or two of aristol; but this is more especially suitable for use in the chronic trouble. Sidney Ringer thinks arsenic very useful when sneezing is a prominent symptom in coryza. It is certainly use-

[1] Read before the Medical Society of Montgomery County, Pa.

ful at a later stage, and as a tonic; and atropia or belladonna is a good substitute as a remedy for this symptom, acting more quickly.

The following formula is excellent.

℞ Quininæ bisulph. . . . . gr. xxx
Ext. belladonnæ
Ext. nucis vom.
Ext. aconit . . . . . āā gr. iv
Acid. arsenio. si. . . . . gr. ss

M. Et. ft. pil. No. xxx. Sig. One pill every four hours.

Another similar prescription is this:

℞ Quininæ sulph. . . . . gr. xviii
Liq. potass. arsenitis . . . . . ♏ xii
Liq. atropinæ . . . . . ♏ i
Ext. gentianæ . . . . . ℈ i

M. ft. pil. No. xii. Sig. One pill every three, four or six hours.

In my own practice, I give at once morphia and atropia, making from one to twenty-four doses out of what is called a tablet triturate, now made by many druggists, containing one-sixth grain of morphia and one-one-hundred-and-eightieth grain of atropia, dissolving it in water—a dose every half hour, if required, according to the age of the patient and the stage of the disorder. The atropia counteracts any ill effect of the morphia, and usually prevents headache. It also tends to diminish the secretion of mucus very decidedly. Both together diminish the irritation, and calm the nervous disturbance.

Should headache arise from the morphia or otherwise, a cathartic may be required. This should be one that is speedy in its action, such as a Seidlitz powder, or the headache may be relieved by caffeine—notably with bromo-caffeine.

If a case of coryza presents itself at a later stage, when the mucous secretion has become thickened or dry, I have found a spray of equal parts of glycerine and rose-water useful, to thin the secretion, the spray being thrown into the nostrils at frequent intervals. Glycerine with spirits of camphor is also useful, introduced by means of a quill brush, as it does not mix well enough to be easily applied with an atomizer.

With the morphia and atropia for the first medication, and with the pills of quinine, arsenic and belladonna for later treatment, nearly all cases of simple coryza will be found to yield in a day or two; and these remedies may be placed within easy reach of persons subject to frequent attacks, and much trouble and subsequent disease will be averted.

VOMITING OF PREGNANCY.

BY ENOS T. BLACKWELL, M. D.,
CEDARVILLE, N. J.

Puerperal vomiting, when severe and protracted, tests to the utmost the endurance as well as the patience of the sufferer. She is obliged to bear not only the inexpressible horrors of the deathly nausea, but also the experiences and prescriptions of all her female friends. The domestic pharmacopœia exhausted, she may learn that the disheartening and weakening things she endures have been declared on high authority to be extremely beneficial to her, looking to the conclusion of her gestation. The suffering woman, who "beareth all things, hopeth all things, endureth all things," accepts the promised boon with such philosophy as she can muster; and may prove its truth or falsity, if she survive the dreadful loss of strength which attends the continuous and exhaustive vomiting, and the malnutrition which results; but the physician who is called on for relief should look beyond the phenomena exhibited by the stomach, and not content himself by attempting to placate that organ through remedies applied to it alone.

The reflex symptoms, which radiate from the pregnant womb, and which are largely due to conditions affecting its inner structure, may also originate from causes situated upon its exterior. Should the practitioner fail, in a rebellious case, to inspect the neck of the uterus, he might, while discoursing learnedly on the impossibility of removing the cause without destroying the fruit of the womb, and while devotedly applying remedies to the apparent seat of the difficulty, namely, the stomach, overlook a patent cause that admits of cure, both signal and speedy. If we are able to locate a cause upon the exterior of the uterus which is easy of access, and which may be successfully combated by remedies acting on well-known principles, we shall pursue a more scientific and rational method than if, satisfied of the internal origin of the reflex action, we try in succession the various drugs recommended, which are largely empirical.

Dr. Llewellyn Eliot, of Washington, D. C., whose therapeutic resources have apparently been directed to the effects of the uterine irritation as exhibited in the stomach (REPORTER, October 8, 1890), rather than to the cause, which may sometimes be sit-

uated at the cervix uteri, and in given cases may be seen by means of a vaginal examination, brings forward a number of cases in support of the internal use of tincture iodi, a remedy recommended by Prof. Laségue, and tested and endorsed by M. Darthier (REPORTER, February 8, 1890, from *L'Union Medicale*). This appears to be an excellent remedy for many cases, but time should not be lost with temporizing measures, and the patient allowed to drift into extremity before an attempt is made to allay the reflex symptoms by local applications to the neck of the uterus. Medicine by the stomach may be continued, if thought advisable. Two cases have come under my observation which illustrate and emphasize this view.

Case 1. March 4, 1886. Mrs. ——, 28 years old, married, and one month advanced in her fifth pregnancy, had had almost constant vomiting from the date of conception. Her experience in all her former pregnancies had been ceaseless vomiting for the first three months, and excessive salivation. She had been promised by her last accoucheur that relief would be afforded her in any forthcoming trouble of that kind. As related to me, I judged that the relief was to be obtained by destroying the fruit of conception. The husband, who called me, hinted at this procedure. I found the patient in an extremely discontented, despondent, and rather savage disposition. She was most forlorn from the incessant vomiting, and greatly dispirited because of lack of sympathy, and of any expectation of help. Her mental alienation and dislike of her husband were complete, and she abhorred his approach. I presented the claims of the intra-vaginal treatment as brought forward by Dr. J. M. Halbert, of Skipworth, Miss. (*Medical Bulletin*, Vol. v, p. 105), consisting of iodide of phenol, or nitrate of silver, fifty grains to an ounce of water, applied to the neck of the uterus. Being in despair, she was ready for any procedure that gave prospect of relief. Examining through the speculum, I found an erosion the size of a nickel five-cent piece upon one side of the cervix uteri, and applied the silver solution in the strength directed by Dr. Halbert. Very great benefit followed the first application. Two days later, the erosion was again cauterized, and cocaine, which had been found successful by Dr. Wm. Duncan in like cases (REPORTER, Vol. lvii, p. 65, from the *Lancet*), was also applied to the abrasion. By March 10, six days from commencing treatment, the recovery was so great that she took a journey to a city ten miles away. The silver solution was reapplied on March 18, and on March 25—four applications in all. From this time the stomach resumed its healthful condition, the gestation being normal to the end.

November 22, 1890, I called upon this woman, whom I had not seen since attending her for the vomiting, four years and a half before. She informed me that she again became pregnant a year ago last March, and that the vomiting commenced immediately, with its accustomed atrocity. Her physician, it seems, had no knowledge of topical applications for subduing this horrible and rebellious infliction. The stomach, therefore, had to endure a round of remedies wondrous in their variety, but alike inefficient. For two months she was confined to her bed, and recovered only when the usual immunity succeeded at the end of three months.

Case 2. July 27, 1889. Mrs. McP., a young primipara, applied for treatment for puerperal vomiting. She was given the following:

℞ Potassii iodidi . . . . . ʒij
Aquæ . . . . . f ʒiv

M. Sig. A teaspoonful in hot water, every few hours.

She was commended to pop-corn, and also, I think, to buttermilk, which figure in the list of empirical remedies. No relief having occurred, on August 2, I applied the vaginal speculum, and discovered an erosion similar to that in Case 1. An application of the silver solution, fifty grains to an ounce of water, having been made, great amendment promptly followed. So complete was the amelioration, that the patient did not desire further help. Before the month closed a diarrhœa came on, which resisted ordinary remedies, and persisted to the end of the gestation. Whether this was due to uterine irritation transmitted to the bowels, I know not. Its intractability would seem to indicate this.

She did, indeed, *think* that she had received some advantage from cocaine taken by the mouth; but, as its use was persisted in until the cocaine habit was formed, it is quite improbable that any benefit was derived from it sufficient to compensate for the danger incurred.

New York Correspondence.

NEW YORK LETTER.

Contribution to the Pathology of Reynaud's Disease.—Removal of Hypertrophied Prostate.— Trephining for Epilepsy. — Total Extirpation of the Larynx. — Artificial Larynx.—Remarkable Case of Luxation of the Patella.—Chronic Cervical Adenitis in Children.

The holidays and the electing of presiding officers for the year, have somewhat hampered the scientific work at the New York Academy of Medicine. As of general interest in New York, however, since last report, may be mentioned a contribution to the pathology of Reynaud's disease, by Dr. G. W. Jacobus, read before the New York Neurological Society. He said that although a great deal had been written upon the subject of local asphyxia and symmetrical gangrene since Reynaud first drew attention to this disease, and very many new cases of the affection had been described, the knowledge at the present time of all of its features, except, perhaps, the purely clinical ones, was hardly any more advanced than it was at the time of Reynaud's writing. Etiologically we had in a certain sense made some progress, for now we realized that other causes than those which Reynaud believed to be the only admissible ones, might have a supplementary productive action. As it was recognized that the symptoms of local asphyxia and symmetrical gangrene were often due to unrecognizable states of disordered blood mixture, the author simply touched upon this point. He said that upon the question of anatomical nerve disease as a cause of symmetrical gangrene there could not be any uncertainty. That the nerves did exert a certain amount of influence upon the production of gangrene, either indirectly by affecting a contraction of the vessels, and thus suppressing the nutrition of the part (Reynaud) or by producing it independently of the vascular system, could not be denied. According to the assertions of Quesnay, section of the nerves was said to produce gangrene of those parts in which they took their course. This assertion had been made repeatedly since then, but the proofs were wanting on account of the impossibility of completely cutting through all the nerves of a part and leaving the arteries uninjured. On the other hand a clinical proof of this dependence was found in the fact that gangrene of an extremity occurred, after ligature of an artery, more easily if the nerve had been injured than if this was not the case. As stated, in order to make a diagnosis of symmetrical gangrene in Reynaud's sense, we must be able to exclude gross nerve disease. This could not be done in many cases. The class of cases which the speaker dealt with were those which came under the caption of gangrene, due to pathological changes in the blood-vessels. It was a *sine qua non* for the diagnosis of Reynaud's disease that the lumen of the vessels should be free, and that their walls should be found in a healthy condition, so that vascular disease might anatomically be excluded as a causal agency in the production of this affection. If, with this in mind, we reviewed the various cases reported, we should find that although pathological examinations had not been frequently made, still in a number of cases in which this had been done, the condition of the arteries did not fulfill the required obligations. All cases of spontaneous gangrene, symmetrical or unilateral, would require careful attention and examination. In many cases we would be able to discover some local change in the arteries of the affected parts, while in others some general affection of the arterial system would explain the gangrene. Many cases would, however, always remain in which, no matter how careful the examination, no such explanatory conditions could be detected. There were still other cases, which in view of the fact that many of the so-called cases of Reynaud's disease were not symmetrical, and might be ascribed to nerve influence, which were better explained by the assumption of an obliterative endarteritis. It was well known that syphilis produced upon the arteries a periarteritis which gradually encroached upon their entire diameter, finishing as an endarteritis and thus narrowing or even totally obliterating the caliber of the vessel. It was also well known that many cases of spontaneous gangrene, resembling Reynaud's disease in every particular, were often due to such affection of the arteries. What was known about the symptomatology of syphilitic affections of the superficial arteries, as revealed by a study of the few published cases, was as follows: Two phases of the pathological changes found a clinical expression, and obliged us to differentiate a stage of induration, with preservation of the lumen of the artery, and one of obliteration

of the artery with all its consequences. In the obliterative stage we had symptoms of ischæmia progressing in extent according to the seat of the affected arteries and according to the difficulty encountered in the establishment of the collateral circulation; if the terminal arteries of the extremities were affected, the disorders would be very marked, consisting in œdema, slight syanosis, reduction of temperature, and finally we might also have gangrene of the parts. If, however, small arteries were affected whose collateral ramifications could be replaced, then the symptoms would be transient or entirely wanting. From a consideration of the various data; from the nephritic as well as from the syphilitic cases; we were unavoidably forced to the conclusion that those authors who admitted that an affection of the small arteries, be this artaritis obliterans or other change, did produce a similar clinical picture to that found in Reynaud's disease, herein were right, but that these same authors were wrong when they contended that a differential diagnosis between the two affections could always be made. The points which were adduced by the various writers for the purpose of making this differential diagnosis were the following: Gangrene occurred in some cases of Reynaud's disease in places where endarteritis obliterans had thus far never been described. The lesion in many cases of Reynaud's disease was confined to the superficial layers of the cutis, and this never occurred in endarteritis obliterans; the absence of those etiological movements which produced vascular disease, as syphilis, absence of all palpable anatomical changes in the vessels; and finally, the occurrence of symmetrical gangrene in neuropathic individuals only. That these points were invalid and some of them erroneous became clear when we considered that it was probable that arteritis obliterans occurred in the vessels of the skin, a condition which had been pointed out by Klotz and Hutchinson. From these facts we were justified in concluding that the differential diagnosis between Reynaud's disease and anatomical disease of the arteries could, in many cases, not be made intravitam, or in other words, many of so-called Reynaud's disease were really cases of arteritis.

Before the Surgical Section, Dr. R. F. Weir showed a middle-aged man from whom he had removed a hypertrophied median lobe of the prostate gland. The patient had been for a long time in the habit of using a catheter, which had at length broken, leaving a portion of it in the bladder. Symptoms of stone had subsequently developed, for which the speaker had performed supra-pubic section, and had extracted from the bladder a good-sized stone, of which the broken catheter had formed the nucleus. On illuminating the interior of the bladder he had discovered a projection enlargement of the prostate gland which he had removed. The resulting hemorrhage had been checked by lessening the pressure of the water bag distending the rectum. The bladder was then packed with iodoform gauze. The case had gone on to a complete and satisfactory recovery, with entire restoration of the normal functions of the part. In the event of his having to do this operation again he should make use of the tonsillotome in preference to any other cutting instrument, in removing the glandular enlargement.

Dr. A. P. Gerster said that it was not always the cases of operative interference of the prostate gland which were as successful in their issue as that reported by Dr. Weir. Half the patients in whom the middle lobe was removed did not recover to such a degree. This was due to the fact that the contractile powers of the bladder were gone. The removal of the lobe could not restore the muscle. The operation was not always a proper one, and great judgment was called for in the proper selection of suitable cases.

Dr. Weir also presented a man fifty years of age, who had suffered for a number of years with frequently recurring epileptic attacks, resulting from a depressed fracture of the skull. A primary operation had been performed which had been of direct benefit, but as the patient complained of constant pain, a second one was undertaken, in which a very extensive flap was raised, and three buttons of bone removed. These were replaced and the interstices filled with bone chippings. The result of this part of the procedure was good, firm union with the exception of a small point of softening at which pulsation could be felt. The epileptic seizures had been reduced from several each day to about one a month, and the patient was able to attend to his business. This was the usual outcome of all operations for epilepsy of this character, improvement might be looked for, but very seldom cure.

Dr. Robert Abbe thought in the class of epilepsy to which reference had been made repeated trephining was likely to be of direct benefit. He had operated upon a case

about a year ago and had relieved the patient from an impending condition of insanity in which there had been half a dozen maniacal seizures a day. It had been six months before a recurrence had taken place. The patient was then put in an asylum. Repeated operation might have been of signal utility in this case.

Dr. Willy Meyer exhibited a patient sixty-five years old, upon whom he had recently operated, removing the entire larynx, for epitheliomatous growth. The man was now wearing one of Gussenbauer's artificial larynx tubes. As this had only been in place fourteen days, the patient, although already able to articulate and make himself understood, could not do so as well as he undoubtedly would, by reason of the non-closure at present of a small part around the tube, with some escape of air. The speaker thought that the larynx he had adjusted would amply meet the needs of a patient of this age.

Dr. Townsend then presented quite a remarkable case. He placed a young colored girl in a chair upon the platform and baring her left knee he stated that she had suffered from what was said to be congenital dislocation of the patella of that joint. As she grew up the patella would become spontaneously dislocated either on one side or the other whenever she attempted to run. But this was not all, she was capable also of causing dislocation by voluntary muscular effort. As she had been for some time under treatment this power was lost as to the inner side. He then directed the girl to effect the dislocation, when to the astonishment of everybody, and apparently without the slightest effort, she shot the patella to the outer side of the joint, bringing it back into position, repeating the performance at will.

Before the General Session, Dr. A. Jacobi, in a paper on chronic cervical adenitis in children, said that the frequency of the morbid changes in the lymphytics was explained by the large amount of cells which formed the bulk of their structure. They were still similar to the embryonic cells, increasing and proliferating as rapidly. Therefore, tumefactions were brought about very readily. As an intricate network of blood-vessels penetrated their follicular substance, they might undergo morbid changes through the intervention of the blood. When the latter was the cause of disease, the whole system of lymphatics was likely to be affected simultaneously. This was, however, rare. In the majority of cases only groups of lymphatics, or single lymph bodies, were affected. The cause of the disease must be looked for in the circulating lymph which, both in normal and abnormal circumstances, was retained and filtered in the lymphatics. These were not open tubes, but a fine network of cavities lined with endothelium. Foreign bodies of any description floating in the lymph were there retained and underwent changes. There were also chemical changes in the lymph itself which would irritate the lymph body and provoke disease. Thus it was that most of the morbid changes of the lymphatics were secondary in character. Such changes were almost always the result of, or complicated with hyperæmia and inflammation. The lymphoid cell constituents increased in different ways. Leucocytes were retained in large numbers, lymph-cells floated in, a subdivision took place, and the endothelia and cells were changed into similar or equal organic particles.

This condition might undergo restitution, or a lymphatic induration might take place through nucleæ proliferation in the stroma, and again suppuration or necrosis might occur. The fibrous induration was the more frequently met with in the bronchial, tracheal, mesenteric, axillary and inguinal glands than in the cervical. In the inguinal it was very common and was frequently met with in this region without any morbid symptoms. This change exhibited often a chronic character from the beginning. The glands were not always enlarged, but were white and hard on section, with thickened capsule, the cellular substance seemed to be diminished and the gland appeared to consist more or less of connective tissue only.

The suppurative change might be confined to the gland, at least temporarily, or the neighboring tissues participate in the process at an early period. Small abcesses originated mostly in the follicular substance, might prove confluent so as to form larger abscesses and finally burst or were incised. Recovery took place by a shrinking process, by cicatrization, by the formation, when the larger lymphatics were injured, of a fistula, sometimes accompanied with lymphorrhœa, or by dessication, or caseation, or calorification. This was the second form of chronicity. The third form of chronic adenitis was the caseous, which generally occurred under the influence of scrofulous

or tuberculous predisposition. It was usually found in the cervical, bronchial and mesenteric glands.

General infection of the glandular system might act through the blood as in any putrid and septic invasion, in anthrax, lepra, leucocythemia and pseudo-leucocythemia, under the influence of Koch's lymph, in syphilis, and in enteric fever. In the two latter, the local irritation resulted in local glandular affection, by preference. Still more local was the action of the diphtheritic virus. The majority of cases of adenitis owed their existence to a local influence. In many instances the study of the origin was single, in others, particularly in cases of long duration, the connection of chronic adenitis with its original source was no longer traceable. In a child, therefore, of advanced years, and the adult, the history of chronic cervical tumefaction might be quite obscure, in the infant and young child the elucidation of the etiology was generally simple. The best protection against adenitis in any of its forms was the preservation of good general health and the absence of any breaks in the integument. Traumatisms, insect bites, erysipelas, and so on would start an adenitis directly. Pediculi, eczema, or impetigo capitis would do the same thing, heal these, and, contrary to the public prejudice, most of the glandular noduli and nodi would disappear. Among other common causes given by the speaker were many of the ear and eye troubles, various forms of zoster, fever blisters and so on. Any condition interfering with the healthy state of the mucous membrane might give rise to adenitis. This was especially true with regard to the nose and naso-pharynx. Boring at the nose, from reflex intestinal irritation by worms, was likely to set up a chronic adenitis. Simple douches of salt and water were the best treatment for these nasal irritations. There was no better illustration of the way an adenitis would come and go in the presence of proper treatment than in nasal diphtheria. As fast as the glands swelled, just so rapidly would they diminish under the influence of cleanliness and disinfection, while, if not so reduced, their infection would lead to death or chronic changes. Cracked lips permitted the invasion of microbes and the development of adenitis. Epithelioma, stomatitis of every form, the denuding of the surface by a burn, or by hot food, were all causative. Abrasions of the surface of the tongue through catarrh or inflammation, or the surface lesions of infectious diseases might all provoke adenitis. Drugs would also produce the same effect. Chronic bronchitis resulted in swelling of the mediastinal glands; their intimate connection with the lower tier of the cervical affected these. This observation could be made in the chronic bronchitides of the tubercular and rachitic babies in many instances. Acute pulmonary diseases exhibited similar results. The vaso-motor changes of the face, its flush lasting for days, generally unilateral, on the side of an acute pneumonia were well known, not so commonly known, however, as the tumefaction, of cervical glands in cases of pleuro-pneumonia of the upper lobe. This disease had an immediate influence upon the intra-thoracic lymph-bodies adjacent to the apices, and through them on the subadjacent cervical lymph-bodies.

While touching upon the question of diagnosis, the speaker said that the sensation of fluctuation in glandular swellings was often misleading. Large glands might be mistaken for sarcomata and *vice versa*. These latter pseudoplasms yielded a peculiar apparent fluctuation, though there might be no cystic complication. This semi-fluctuation was almost characteristic for sarcomata in every region. It was always a difficult thing to determine the presence of pus during the stages of initial softening. Still less was there absolute certainty in every case of the presence or absence of a malignant nature in a large glandular swelling. This difficulty was made very apparent by the variety in the morphological diagnosis by the morphologists. The gradual increase in size, however, of a tumor, without softening, spoke for the probable malignancy of the growth. The presence of more swellings of the same character on other parts of the body, might prove the existence of Hodgkin's pseudo-leucocythemia, and the same with enlargement of the spleen or liver and the characteristic changes in the blood might indicate leucocythemia.

—At the Eiffel tower a steel ball weighing 211 pounds is, by a bronze wire 380 feet long, suspended from the second platform, and allowed to swing near a layer of sand. Under the ball is a style tracing a mark in sand at each oscillation. The apparatus serves as a popular demonstration of the earth's rotation.

PERISCOPE.

Simple Medication for Children.

Under this title Dr. Charles Warrington Earle, of Chicago, made some admirable remarks at the meeting of the American Pediatric Society last year. From the report of his paper in the *Archives of Pediatrics*, January, 1891, the following extracts are presented.

I believe in medication always, when needed, but at the same time belong to that class of physicians who believe it quite as much my duty to say to people, "You need no medicine whatever," if such be the case, as to prescribe a heroic dose when it is indicated. When, however, good diet, a better hygiene, more air and sunlight will not suffice to save, and it is necessary to give medicine, we owe it to our patients, especially our little patients, to prescribe a drug or drugs so that they shall be cured not only quickly and safely, but, if possible, pleasantly.

In the first place, many cases to which we are called need no medication whatever; that is especially true of first visits. There is a little irritative fever, a slight indigestion, a trifling nervousness, a few more bowel movements than usual, or the mother simply imagines in her solicitude that the baby is threatened with something. Many conditions similar to these are frequently seen, and they will recover—correct themselves without medicine; indeed, better without than with medicine. The diagnosis is frequently made by a parent, and the doctor is summoned to prescribe for a fever or for malaria, or for worms, and before he sees the little patient he has devised a combination of drugs for it. Something to reduce the pulse; to correct the secretions; something to regulate the excretions. How much better it would be for this little one to give it nothing, for in many cases the patient will be entirely well in a few hours.

I do not advise against the administration of medicines when they are indicated; I know that by the judicious use of a drug, or drugs, diseases may be modified, a convulsion possibly averted. But the indication for its use should be clear—we should not give a drug simply to make a show of prescribing.

In the second place, when a single drug is indicated, we find in many cases too many prescribed, and a child's appetite destroyed and its nutrition impaired by the procedure. This does not apply to diphtheria, or any other disease which, at times, is local, and should be combated with vigor and promptness and frequency in order to keep it from becoming a general disease; but it does apply to that vast category of complaints where it is absolutely necessary to improve nutrition.

Again, take the eruptive fevers during the first stage: why give a little aconite or belladonna to reduce the fever? We want some fever; we all prefer a temperature of 102° to one at 98°. Why unload the portal circulation and, in so doing, probably irritate to a greater degree the already irritated mucous membrane of the alimentary canal? Look out for the throat in scarlet fever, which here will give more trouble than any other organ (excepting possibly the kidneys), and for the lungs in measles. This should, it occurs to me, be the rule in general. Do not waste time and annoy the patient by doctoring a symptom; attack the disease.

And then in convalescence—how much it is retarded by the reckless administration of drugs. After a baby has passed through a fever, or some disease of the lungs, it does not need something to act on its liver or kidneys, or to clear up its tongue which is quite frequently normal when a little coated, or some alkali to correct a fancied acidity; but it does need something to eat, and it can't eat as long as the stomach is filled with nauseous medicines. This condition is well illustrated by a case I saw late in the year 1889. The child, around whom all the love and devotion and nonsense of a young father and mother clustered, had the "grippe." Its temperature had been rather high and the bronchial catarrh really severe. The attending doctor had diagnosticated pneumonia, and for this I was summoned. After a few days it began to convalesce, and I left it with the understanding that some restorative medicines, probably the hypophosphites with a little pepsin and possibly a minute dose of tincture of nux vomica, was to be administered. In two days I was recalled and was informed that the appetite was poor, the pupils dilated, the head was being thrown from side to side, and the doctor and parents were sure that cerebral congestion, if not meningitis, was present. By actual count that child was taking nine different drugs, hardly one of which was indicated. It was having bicarbonate of sodium, iodide of potassium, muriate of ammonia, tincture of aconite,

tincture of belladonna, tincture of camphor, and a little opium, submuriate of hydrargyrum, to which should be added camphorated oil externally, supplemented and strengthened by a plaster of belladonna ointment. Is it any wonder that that child could not eat, that its pupils were dilated? The wonder to me is that it was alive. I solemnly declare that I have been more alarmed for fear that some doctors would kill their little patients with drugs than that the cases would terminate fatally from the disease.

We now come to pleasant medication. Of course, this is not, by any means, an easy task; sometimes it is impossible without sacrificing the usefulness of the drug. With care, however, we can do much; we can avoid prescribing large mixtures, can stop giving tablespoonful doses, and, in many instances, give our tinctures in water. Happily the custom of ordering four, six and eight ounce bottles of medicine has nearly ceased. It should be stopped entirely, except in those cases where tonics and cough-mixtures are given, when it is necessary to see a patient but seldom. In acute sickness it is usually quite all that is needed to prescribe one-ounce and occasionally two-ounce mixtures. In the administration of most of the tinctures, particularly aconite, veratrum, digitalis, as well as Fowler's solution, etc., where the dose is from a fraction of a drop to one or two drops, it is best for the young physician to carry the drug and measure out enough at each visit for the coming twenty-four hours. This gives a pleasant medicine, and it is also economical, and to young practitioners it is a custom which will make them friends. It is good practice, too, for physicians to always be ready to give the first dose of medicine; it may not be much, but it convinces the people that you are ready for emergencies; this I say more particularly to those young in the profession.

With a little care we can treat a case running through several days, if not weeks, with but little display of drugs. Nothing makes the people appreciate the expensiveness of a doctor so much as, at the end of two weeks' sickness, having a tableful of bottles partly emptied. And nothing disgusts the patient to such an extent as to witness the doctor every morning commence to write his usual two or three new prescriptions; a part only, at most, will be taken, the remainder to go to make up the tableful, which is to be removed at the conclusion of the sickness.

Detection of Biliary Matter in Urine.

The American Druggist, December, 1890, says that according to Dr. Adolph Jolles, of Vienna, who has made a comparative study of the various bile reactions so far proposed, the most reliable tests are those proposed by Rosenbach and by Huppert. Rosenbach's test is as follows: A piece of filtering paper is wetted with the filtered urine, and a drop of nitric acid then applied to it. Colored rings will form about the drop of acid.

Huppert's test: Precipitate the urine with milk of lime. Exhaust the precipitate with alcohol containing sulphuric acid, and apply heat. A green color is developed.

Dr. Jolles has found that both tests are capable of improvement. In the case of Rosenbach's he recommends the following modification: Filter a large quantity of the urine to be tested through pure, white filtering paper, then apply to the inside of the filter a drop of concentrated nitric acid containing some nitrous acid, and slowly pass the funnel containing the filter three or four times over a Bunsen burner. After a few minutes observe the rings which will have formed around the drop. If they are colored green, bile pigments are present. The application of a gentle heat reveals even traces of these pigments. The bright-green ring shows the presence of biliverdin.

The reliability of Huppert' test depends mainly upon the strength of the milk of lime. As the author of the test failed to specify it, Dr. Jolles made experiments, and found that the most suitable strength was about 1 per cent—that is, a milk of lime containing about 10 grams of lime in the liter of water. The test is best performed as follows:

About 8 to 10 c.c. of the urine are mixed with an equal volume of the milk of lime, the mixture is shaken, and the precipitate separated by filtration.

So far the *American Druggist* describes the test correctly. For the rest, we give the statement to the REPORTER of Dr. John Marshall, of the University of Pennsylvania. Dr. Marshall says:

"The precipitate from icteric urine is yellow, from normal urine it is white; and from urine containing chrysophanic acid, it is rose-red. The precipitate is now placed in a beaker and boiled with alcohol containing a couple of drops of dilute sulphuric acid, and then the mixture is filtered. In case biliary coloring matter is present, a

beautiful green coloration is imparted to the liquid; while from normal urine the liquid remains colorless and in the presence of chrysophanic acid it becomes orange-yellow."

Leprosy in Colombia.

An official report on the rapid spread of this disease is contained in a recent number of the *Revista de Higiene de Bogotá*. It is the result of systematic medical inquiries throughout the Republic regarding the causes and phenomena of the disease by the Central Junta of Hygiene of Colombia. The propositions of this medical commission are of interest in respect of the primary steps of relief that will be recommended to the executive and legislative departments of the government: 1. To solicit the next Congress to pass a law providing for the isolation of individuals affected with leprosy and elephantiasis. 2. To establish a special tax to defray the expense of observing the method of propagation of the disease and for the erection and maintenance of lazarettos; and to include this tax in the central budget of the government. — *New York Medical Journal*, December 6, 1890.

Sunflower Plantations as a Prophylactic against Malaria.

In the *Vestnik Obshtchestvennoi Hïgïeny, Südebnoi ï Praktitcheskoi Meditziny*, September, 1890, p. 104, Dr. I. D. Imüidzinovitch, of Kopal, Semïretchïë, issues an emphatic appeal in favor of an extensive cultivation of the sunflower (*Helianthus annuus*) in malarial regions. The author's observations fully confirm the statements by Maury, Van Alstein, Martin, Valentin and A. Stüpin, according to which the beautiful plant possesses an extraordinary power of draining a malarial soil, absorbing and destroying the malarial miasms and thus preventing marsh fevers. He adduces the following facts which certainly deserve every attention of sanitarians. The Kopal district, in which he practices, belongs to typical abodes of endemic malarial fevers. In certain villages, however, inhabited by Ukraïne (South-Russian) emigrants who extensively cultivate the sunflower for industrial purposes (for obtaining the sunflower oil, which is largely used as a food article all over Russia) malaria is almost unknown—and that notwithstanding the circumstance that the said villages are situated in exceedingly low and marshy localities. Meanwhile, in all other parts of the district—including all settlements in the neighborhood, inhabited by Cossacks who do not cultivate the sunflower, but otherwise live under exactly the same conditions as the Ukraïne planters—marsh fevers of all varieties are raging to an appalling extent.

Treatment of Erysipelas.

The Lancet, January 10, 1891, says that an elaborate research, clinical and bacteriological, has recently been published by Professor Nussbaum's assistant, Dr. Julius Fessler, on the treatment of erysipelas by ichthyol, a plan which has been for some years extensively adopted in Munich. From laboratory experiments it was evident that, though ichthyol has only a slight effect in preventing the development of staphylococci, it has a very potent deterrent influence on the multiplication of streptococci, and it is well known that it is the latter kind of bacteria that are the cause of erysipelas. The method of treatment consists mainly of rubbing a strong ichthyol ointment energetically, and for ten minutes at a time, into the affected surface and in its neighborhood; ichthyol in the form of pills may also be given internally. Where there is a wound it must be very carefully disinfected, and an antiseptic dressing applied. The results of this treatment as compared with ordinary methods are embodied in several instructive tables. From these it appears that while the mean duration of the cases treated by other methods from 1880 to 1888 was about twelve days, in no single year falling below nine days, the cases treated by ichthyol from 1886 to 1888 presented a mean duration of under seven days, while in the first half of 1889 it fell to 5.6 days.

Resection of the Liver.

On December 8, Professor Iginio Tansini, of Modena, performed total extirpation of a hydatid cyst of the liver, at the same time excising a portion of that organ. There was very free hemorrhage from the large cut surface of the liver, which was controlled by catgut ligatures. The wound in the liver was closed by means of sixteen sutures, partly silk, partly catgut. The operation was followed by no rise of temperature, and the patient (a woman) was quite well in less than a fortnight.—*British Med. Journal.*

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

VARICES OF THE ŒSOPHAGUS.

Vomiting of blood is a common symptom in cirrhosis of the liver. Most writers on the subject ascribe it to capillary oozing, while some, as Bartholow, have met with ulcers opening into veins near the pyloric orifice of the stomach. In a number of cases, however, no lesion has been discovered *post-mortem* to account for the hematemesis that occurred during life. It is asserted by Mr. T. Stacey Wilson and Mr. J. R. Ratcliffe, in a paper on Œsophageal Varices as a Cause of Hematemesis in Cirrhosis of the Liver, published in the *British Medical Journal*, December 27, 1890, that a varicose condition of the veins of the lower part of the œsophagus is a very common cause of hematemesis in cirrhosis of the liver. When one bears in mind that the œsophagus is not usually examined at autopsies, the fact that comparatively few cases in which this condition has been found have been reported is easily accounted for, and does not militate against the assertion referred to.

It is well understood that, as the liver shrinks through the contraction of the interstitial tissue which characterizes cirrhosis, the radicles of the portal vein become narrowed and even obliterated, the result of which is dilatation of the portal vein and its sources. Now the blood which is thus prevented from passing through the liver must seek some other channels by which to reach the vena cava and the heart—the collateral circulation becomes dilated to accommodate it. The nature of the circulation around the lower end of the œsophagus, as Mr. Wilson and Mr. Ratcliffe say, is such as to admit of an intercommunication between the blood and the portal vein, on the one hand, and that of the general systemic veins on the other. For the veins of the cardiac end of the stomach belong to the portal system, while those of the œsophagus belong to the system of the azygos and interior vena cava. Thus the capillaries in the mucous membrane at the cardiac orifice of the stomach are continuous with both systems. This can be proved by means of injections. Now the blood from the cardiac end of the stomach is normally carried to the liver by the coronary vein; but when the passage of portal blood through the liver is hindered, the blood finds an escape through the œsophageal plexus of veins formed by the coronary and the vasa brevia of the splenic vein—and there is, therefore, to a greater or less extent, a reversal of the normal flow in the veins mentioned, but mainly in the coronary vein. From the œsophageal plexus the blood finds its way to the heart through the left inferior phrenic vein, which opens into the left renal, and so it goes into the inferior cava; and through a number of small veins which run on the surface and in the substance of the diaphragm, and enter the cava as it passes through the diaphragm.

The œsophageal plexus already mentioned

is external to the muscular coat of the œsophagus, but there is another plexus beneath the mucous coat, which also becomes enormously dilated under similar conditions, and is of more clinical significance than the former. But enough has been said to show how these veins at the lower end of the œsophagus become dilated and so help to relieve the congestion of the portal system and prevent dropsy. It only remains now to mention, very briefly, that Mr. Wilson and Mr. Ratcliffe report five cases which tend to prove that hematemesis in cirrhosis is produced by ulceration of one of these varicose veins. In three of the cases in which hematemesis occurred, and in one of melæna, there were three that showed distinct ulcers into the veins before injecting, and in the fourth there was an erosion over a thrombosed vein.

In the fifth case there had been no hematemesis and no melæna, and the most careful examination failed to show any ulceration. Ascites was absent is the cases which showed the most marked varicosity.

To complete this subject, as far as it can be completed at present, we must refer to an extremely interesting and beautifully illustrated paper by Dr. Maurice Letulle, in *La Médecine Moderne*, November 20, 1890. This author maintains that cirrhosis of the liver is not the cause of varices of the œsophagus, but that this condition is secondary to the effects of alcohol on the veins which first receive it—the mesenteric and their branches. These become chronically inflamed, thrombosis occurs, and subsequent dilatation of the collateral circulation, including the œsophageal veins. A case which seems to bear out the view indicated is reported, and a very complete summary of the literature given.

Whether varices of the œsophagus are secondary to a cirrhosis of the liver or to an alcoholic phlebitis of the veins forming the portal system, probably cannot be decided now. But as there is no dispute that the hematemesis which occurs in these cases is from dilated veins, the impropriety, from a therapeutic point of view, of attempting to check the bleeding by giving ergot and other agents which constrict arterioles and thus force more blood into veins, becomes manifest. Nitrite of amyl, as suggested by Dr. Saundby, would meet the requirements much better, through its action in dilating arteries and so permitting less blood to pass into the veins. It is evident, also, that the œsophagus must be kept at complete rest, all efforts at swallowing, even of fragments of ice, being prohibited.

EXPLORATORY PUNCTURE OF THE FEMALE PELVIC ORGANS.

In years gone by, when the mortality of abdominal section as then performed was enough to appal even a stout heart, the necessity of making an absolutely exact diagnosis was far more important than it is at the present time. Then the advantages of a proposed operation had to be weighed in the balance against a prospective mortality of seventy-five, fifty, or finally twenty-five per cent. Hence it was justifiable to operate only for conditions in themselves necessarily fatal, and to select the most favorable cases. The use of the aspirator was considered to be a most desirable way of differentiating between various pelvic growths. Experience showed, however, that the information gained by the use of the aspirator was often far from satisfactory, and that even after its use a positive diagnosis was often impossible. Moreover its use was not free from danger. With the introduction of modern aseptic surgery, the danger attending simple exploratory abdominal section became so slight that surgeons have employed this method of diagnosis in obscure cases, affording as it does at the same time an opportunity to effect a cure. Exploratory puncture has fallen more and more into disrepute—being regarded as an uncertain method of diagnosis at the same time being more dangerous than exploratory abdominal section.

At a recent meeting of the New York Academy of Medicine, Dr. G. M. Edebohls read a paper in which he gives his experience with exploratory puncture of the female pelvic organs, and attempts to make the method again popular with the profession. He prescribes an elaborate technique: full antisepsis, outlining and fixing the mass to be punctured, and puncture with the aspirator syringe from the abdominal surface. Seventy cases are reported in which the method was employed without untoward results. The author advises that the method be used only by the expert, lest harm rather than good result. In the discussion, in which Coe, Dudley, Boldt, Murray, Jewett and others took part, the method met with decided opposition on the ground that it is a question whether it is right to expose a patient to the danger of puncture of the intestines, with consequent peritonitis and probably death, where it is possible to secure such good results from abdominal section if a diagnosis cannot be made without an exploratory operation of some kind. This opinion is undoubtedly in accord with the sentiment of to-day. If it be possible to so outline a mass as to be able to fix it with the examining fingers for exploratory puncture, it should be possible to form an intelligent opinion as to its nature. It is the "masses" which cannot be outlined, definitely, and which consequently are not adapted for exploratory puncture, concerning which there will be the most doubt; which doubt, in proper cases, must be cleared up by abdominal section. Finally, it is to be hoped that the method proposed by Dr. Edebohls will never become popular, as its possibilities for harm far outweigh its possibilities for good.

ATLANTA MEDICAL AND SURGICAL JOURNAL.

In its January issue the *Atlanta Medical and Surgical Journal* expresses the great pleasure with which it appears before its readers free from "inserts," or pages of advertising interspersed among its pages for scientific matter; and the REPORTER expresses also a pleasure that so admirable a contemporary has thus emancipated itself. The scientific and ethical standing of the *Atlanta Journal* is so high, and it has been such an exponent of honest medical journalism, that we congratulate it and the section of the country which it represents upon the improved appearance and more satisfactory standard to which it has advanced.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

THE PRACTICE OF MEDICINE; OR, THE SPECIFIC ART OF HEALING. By I. J. M. Goss, A. M., M. D., Professor of the Practice of Medicine in the Georgia Eclectic College of Medicine and Surgery, etc. 8vo, pp. xxix, 569. Chicago: W. T. Keener, 1888. Price, $5.00.

We find it difficult to review this book and do full justice to our readers and to Dr. Goss. The latter appears to think that remedies should be prescribed according to the pathological indications in each particular case. "The old rule of treating disease by name . . . has," he says, "proved a blighting curse to the unfortunate sick." He is also a believer in the doctrine that there is a direct or specific affinity of remedies for certain organs, tissues or parts. He seems to believe, to some extent, in Hahnemann's law of similars, but he refers to the latter's belief that dilution rendered medicines more potent as "the vague chimera of this great man."

The actual value of the book, judged by the scientific standards of the day, is not great. It is scarcely more than a compend, in which diseases are not grouped in an orderly manner, and in which undue prominence is given to mere symptoms. For example, the title of Chapter IX is "Fevers: the Exanthemata," and the first disease considered is "Malarial Hæmaturia." Whooping-cough is considered under diseases of respiratory organs, impotence under diseases of the testes, and spermatorrhœa and "onanism" (so Dr. Goss miscalls masturbation) under diseases of the prostate. The author, as was to be expected, devotes most space to treatment. The value of many of his remedies we cannot pretend to speak of, but we fear some of his statements must be accepted with caution. In speaking of the treatment of phthisis, he says that, in 1862, he gave to a patient who was bed-ridden and in the advanced stage of phthisis, "the larger portion of both lungs" "filled with tubercles," hypo-phosphites, ptelia and euonymus. The patient is said to have mended from the first week or two, finally recovered, and to be now a "*living monument*" of the efficacy of the above remedies. Dr. Goss adds that he has recently treated several cases with like success. It may be that his diagnosis was wrong, or that in the lapse of years his memory has made the gravity of the case appear greater than it really was.

The character of the book is perhaps well illustrated by the section on diabetes mellitus, which occupies

only a little less than two pages, two-thirds of which is given to treatment. The author says he cured a case of this disease by giving the patient thirty drops of fluid extract of rhus aromatica three times a day for several months. The urine of this patient yielded, upon evaporation upon a slip of glass over a lamp, "a large percentage of molasses."

The book as a whole is an odd mixture of good and bad, and it is difficult to separate one from the other. We do not think it of any value from a scientific point of view, but are willing to believe that many of the remedies it recommends, which are used almost exclusively by so-called Eclectic and Homœopathic practitioners, may be very useful.

A CLINICAL STUDY OF DISEASES OF THE KIDNEYS. By Clifford Mitchell, A. M., M. D. 8vo, pp. xii, 431. Chicago: W. T. Keener, 1890.

The author presents a large amount of useful information in this book in such a way that it is easy of appropriation by beginners. His statements regarding diagnosis and prognosis are, in the main, correct and judicious. We think, however, he is wrong in looking upon large tube casts as occurring especially in chronic nephritis; large epithelial casts are common in acute nephritis. The granular casts depicted by the author are far too black and dense; they would be taken by any one, if seen in the urine, for blood casts. The object figured on page 70 as an epithelial cast is not a cast at all; it has no body, and is merely a line of epithelial cells.

There is much of value in the parts of the book devoted to therapeutics. Standard authors on renal diseases are quoted freely, and so are Homœopathic writers. The author appears to be truly catholic in his therapeutics. This fact adds considerably to the interest of the volume. Practitioners of so-called eclectic medicine will probably find Dr. Mitchell's book very much to their taste.

TUBERCULOSIS, OR PULMONARY CONSUMPTION: ITS PROPHYLAXIS AND CURE BY SURALIMENTATION OF LIQUID FOOD. By W. H. Burt, M. D., Author of *Characteristic Materia Medica*, etc. Small 8vo, pp. 223. Chicago: W. T. Keener, 1890.

The author of this book, having noticed that it is possible to reduce the weight of a fat person by restricting his use of liquids and carbo-hydrates, was struck with the idea that abundance of water with carbo-hydrates might cure all wasting diseases, especially tuberculosis. He states in his introduction, from the results of his tests, that superabundance of liquid food, which he calls "suralimentation," when used in the first and second stages of phthisis, will enable the physician to cure more than fifty per cent. of the patients that would have to die with the best methods known to medical science up to the present date. After this astounding statement, we are surprised to find the author admit that, in the third or last stage, it will give only temporary relief. Under the etiology of tuberculosis we find the following: "To me its neural origin is as plain as any fact in pathology: its real cause being a debility pareses (*sic*), or neurasthenia of the organic nervous system." The sort of proof which appears to satisfy the author may be judged from the following statement: "The strongest argument that can be used against the bacillus theory is this: cod-liver oil has cured thousands of cases of phthisis. The attenuated homœopathic remedy has cured many thousands of cases, and the suralimentation of liquids have (has) cured many cases." As this statement stands, it would appear that the attenuated homœopathic remedy has been more efficient than either cod-liver oil or "suralimentation." Then why not use it, and why not make its virtues known, rather than those of a less-efficient remedy? But the truth is, quite apart from the truth or falsity of the bacillus theory, that no remedy at present known to science has, of itself, cured a single case of pulmonary phthisis. The most that cod-liver oil or any other food can do is to improve the condition of the patient and help him to overcome the disease.

To conclude—the book is a mixture of sense and nonsense which is not worth reading.

Correspondence.

Double Opening into Womb.

To the Editor.

Sir: Mrs. D—— before she was married fell from overhead in a barn, landing on her feet on the barn floor. As a result she had procidentia uteri, for which she was treated by different physicians.

She wore a pessary—what kind she does not know—but so long that she says it had to be removed on account of ulceration produced.

She first consulted me when pregnant and threatened with miscarriage in 1888, and then I found on examination that she had an artificial opening into her womb at the juncture of the neck with the body posteriorly, which would admit the points of my index and middle fingers. During her miscarriage and in her confinement two weeks ago I found it no particular obstruction to labor, though it caused a good deal of anxiety.

The miscarriage and confinement cases are as follows. On December 22, 1888, I was summoned in the night by Mrs. D—— for uncommon cramps, as she called it. On questioning her, I ascertained that she was pregnant, and gone four months. On examination I found that she had all symptoms of miscarriage, and I also found that she had a second opening into her womb, from which membranes were protruding, it being dilated very much. I administered a full dose of fluid extract of ergot, and had no difficulty in delivering her of the product of conception, the placenta and the membranes. She made a speedy recovery. I suggested operation, but she would not consent.

In course of time she became pregnant a second time, and after having gone four

months she consulted me for symptoms of another miscarriage. I administered anodyne and she went to term.

On the night of December 4, 1890, I was again summoned, not for cramps but, as she then very well knew, with symptoms of labor. On examination I found the artificial os dilated as large as a silver dollar, while the natural os admitted only my index finger. In vain I tried digital dilatation.

Labor progressed, with a head presentation, but disproportion between it and the maternal parts prevented termination by natural means. I administered chloroform and applied the forceps and delivered the woman of a big boy baby through the artificial os uteri.

The mother made an uncomplicated recovery.

The womb and all maternal parts assumed their natural proportion as before delivery, no tear occurred in the neck of the womb.

This case I report to ascertain whether there are any more cases like this.

Yours truly,

A. T. Welker, M. D.

Collomsville, Pa.

Notes and Comments.

Koch's Lymph.

The *New York Med. Journal*, January 17, says: It seems that Koch was guided to his discovery by observing the action of tubercle bacilli, living or dead, on tuberculous and non-tuberculous guinea-pigs. In the healthy animal an inoculation of the pure cultivation gives rise, after a period of incubation varying from ten to fourteen days, to a hard nodule, which soon breaks down into an ulcer and persists until the animal dies. When, however, a guinea-pig already tuberculous is thus inoculated, no nodule forms, but the superficial tissue at the place of inoculation becomes necrosed and falls off. Injections of a quite dilute glycerin infusion of a pure cultivation cause the animal's condition to improve. Evidently, having got thus far in his observations, Koch was unable to overlook the obvious suggestion that even dead bacilli, or at least a solution of some of their constituents or products, contained something that might be made available as a drug and produce the same effect. It was then, therefore, a comparatively simple matter to arrive at the production of the curative liquid now in use. We see no reason why it should not now be prepared in any well-equipped bacteriological laboratory, and thus the restriction heretofore put upon its general employment be ended. In the absence of a more detailed account of its preparation than Professor Koch gives, it may, we think, be assumed that any person who would consider himself conversant enough with bacteriological methods to attempt the work of producing such a liquid would not, even without a hint as to the steps in the process necessary, have been in the least likely to produce an agent more dangerous than the Koch liquid itself. But Professor Koch feared such an occurrence when he first promulgated his method of treating tuberculosis; and his judgment was deferred to by the medical profession. He now brings up in support of his previous secrecy the argument that the less the clinicians knew about the nature of the liquid the more unbiased would they be in their observations of its action. This strikes us as odd, but there may be men so constituted. At all events, we are glad that the nature of the remedy has now been made known. The question of its curative action is still far from being settled.

[The observant reader will observe that Koch has not yet told just *how* he prepares his lymph. The whole affair is much more marked by forbearance on the part of the profession than by scientific candor on the part of Koch.—Editor of Reporter.]

Mutual Aid Association.

The recent meeting of the Philadelphia County Medical Society, at which the claims of and objects of the Mutual Aid Association were especially presented, was an occasion of unusual interest and awakened much enthusiasm. Addresses were made by Drs. Gouverneur M. Smith and Henry Tuck, of New York, the former and present incumbents of the presidential chair of the New York Society for the Relief of the Widows and Orphans of Medical Men, and by Professors Keen, Pepper, Willard and others of this city. A brief memoir of Dr. Henry H. Smith, the founder of the Association, was read by Dr. Benjamin Lee. Sixteen of those present followed the example of Professor Keen in enrolling themselves as members, or increasing the grade of their mem-

bership. The total addition to the Benevolent fund thus made will amount to about $1,300. On the adjournment of the business meeting a reception was extended to the guests from a distance, at the University Club.

The following extracts from Dr. Smith's address will convey an idea of the scope of the work of the New York Society.

"Our Society has, for a number of years, proved a blessing to its beneficiaries, and has been remarkably successful in accumulating a financial capital of $172,180.58, which insures a continuance of a laudable work in the future." After emphasizing the somewhat remarkable fact that the largest contributors to and most earnest supporters of their Society had been bachelors, and mentioning the names of the eminent physicians who in the year 1842 met to inaugurate the movement, he continued: "Do not for a moment suppose that since then it has been fostered by lesser dignitaries. Many of those who have given to it the most time and care have been men whose families would, probably, in the ordinary course of events, never derive any pecuniary benefit from it. Since 1877, the smallest number of widows aided in any one year has been ten, and the largest number fourteen; the smallest number of orphans four, and the largest number eight. During the year the Society meets once. The Board of Managers and the Standing Committee hold four stated meetings, and such special meetings as may be necessary. One matter should be especially emphasized, viz., a *charitable* element should prevail in the direction of such fraternities; while business principles should be strictly enforced in the investments of funds, a charitable disposition should be made of the revenue derived from such funds. The affluent members of the profession should deem it a duty to their holy calling to foster any such organization. It is a work in which men of all nationalities and creeds can mutually co-operate, remembering the words of the great poet:—

'In Faith and Hope the world will disagree,
But all mankind's concern is Charity.'"

Testicle Therapy for Phthisis.

At the meeting of the Paris Société de Biologie, December 20, 1890, Dr Brown-Séquard declared that charlatans were selling under the names "elixir" and "tonic syrup of the nervous system," a liquid which they pretended contained the principle which he has announced as possessed of considerable dynamogenic power, and which is found in a liquid extracted from the testicles and spermatic ducts. Brown-Séquard protests against such deception of the public. The preparations to which he objects are all directed to be taken by the mouth and thus introduced into the stomach; but the gastric juice digests the fluid and destroys its dynamogenic powers, so that, even if the preparations actually contain what they profess to, they would be inert in the way they are administered. To be effective, the fluid must be injected under the skin or into the rectum.

Brown-Séquard also announced that a year or more ago several physicians had treated patients suffering with pulmonary tuberculosis with hypodermic injections of the testicular liquid, and that they had obtained very remarkable curative effects. Brown-Séquard, however, refuses to admit that phthisis can be cured with the fluid, though he does admit that, by virtue of its dynamogenic power it may produce a great increase of strength, cessation of fever and sweats, and a notable improvement in digestion and nutrition, and in the secretions. At Brown-Séquard's instance, Goizet has been experimenting since June last with the injections in phthisis. In three patients with phthisis in the second degree, the symptoms have disappeared and there has been a gain in weight and notably in strength. Dr. Uspensky has also called attention to this method of treatment. He reports that in thirty patients there has been obtained a disappearance of the symptoms of tuberculosis and a notable gain in strength and in weight. Brown-Séquard adds, that where the fluid has been filtered with care and used with proper antiseptic precautions, there is no fear of any dangerous febrile or other reaction.

Resection of Thyroid for Exophthalmic Goitre.

The *Lancet*, January 17, 1891, says that in a recent number of the *Deutsche Med. Wochenschrift*, Dr. Lencke, of Hamburg, discusses the subject of exophthalmic goitre with special reference to its treatment. He claims that as the treatment of this condition by medicine is remarkable for nothing so much as its inefficacy, if the surgeon can offer even a chance of relief his inter-

ference is justifiable, and he relates two cases in which surgical interference seems to have had the best results. The first patient was a lad of seventeen, who had the classical symptoms of the disease—rapid heart, palpitation, prominence of the eyes, and goitre. He came under treatment on account of a sudden access of the swelling, which by the pressure it exerted produced great distress, with extreme cyanosis. The heart was rapid and irregular, no rest or sleep could be obtained, and the patient was in imminent danger of asphyxia. Tracheotomy was performed, and a week later one-half of the tumor was extirpated. The operation was accompanied by much hemorrhage, which, however, stopped spontaneously, and recovery was uninterrupted. The symptoms rapidly vanished, the exophthalmos disappearing and the heart becoming quiet and regular in action. The improvement was maintained until the time at which the paper was written. Operation was undertaken in the second case, which had long been under observation, because of the good result in the first. The patient in this case was older, the symptoms were similar, and the operation was the same. The improvement was also very marked, and the patient four months ago was able to resume his occupation. It is yet too early to estimate the full value of the procedure adopted, as regards cure of the disease; but if relief can be afforded in other cases as great as was apparently obtained in those just related, a strong case will have been made out for the surgical treatment of this distressing malady.

Practiced Medicine without Registering.

In Court, at Reading, February 2, Judge Endlicht decided an interesting case. He refused a new trial to Mrs. Catharine Ebbert, of that city, charged and convicted of practicing medicine without registering, and ordered her to appear in Court for sentence. Mrs. Ebbert has since registered. She says she has been in continuous practice since 1858. In the particular case in which she was convicted, she alleged that the compensation she received was for a box of salve only, and not for medical services. Judge Endlicht says in his opinion: "Whilst it may be true that one who undertakes to cure disease by mere manipulation is not engaged in practicing either medicine or surgery, it is at least equally true that the practice of medicine includes the application of medicines for the purpose of curing, mitigating or alleviating diseases."

Sanitary Convention of Pennsylvania.

The Fifth State Sanitary Convention of Pennsylvania will be held at Altoona, Friday and Saturday, May 15 and 16, 1891, under the auspices of the State Board of Health, assisted by the Board of Health of Altoona and a committee of citizens. This is not, in any sense, a doctors' convention. All who take an intelligent interest in the promotion of sanitary reform and the protection of the public health are invited not only to be present and take part in the discussions, but to forward to the Secretary, Dr. Benj. Lee, 1532 Pine street, Philadelphia, for consideration by the Committee of the Board, not later than April 15, papers on sanitary or hygienic subjects, which they would like to present before the convention.

Habitual Abortion.

The *British Med. Journal*, Dec. 20, 1890, states that at the meeting of the Obstetrical Society of London, Dec. 3, 1890, Dr. Leith Napier read a paper on habitual abortion. Some authorities assert that "habitual" abortion is often due to indefinite sources of uterine irritation impossible to recognize. Others esteem syphilis as the most common cause of habitual abortion. Both views are disputed by Dr. Napier. Apart from disease, malformation, or physiological incompetency, there is no "habit" of aborting. The pathology of "habitual" abortion is the same as that of ordinary or single abortion. Turning to etiology, Dr. Napier showed that more than half the cases were due to uterine congestion or disease, and only 9 per cent. to syphilis. Reflex causes were discussed; at most only 7 per cent. were truly reflex. Syphilis is much more commonly the factor of premature birth than of abortion. Seventy-seven per cent. of women subject to "habitual" abortion are either nulliparous gravidæ, who begin their obstetric career by frequent abortions; or multiparous women, who often terminate fecundity by repeated abortions. Women

who habitually abort are, as a class, very fertile. "Habitual" abortion is highly amenable to treatment. Over 67 per cent. of the patients were delivered at term after cure of the cause of the "habit." Dr. Napier, in reply to a question, said he had wholly avoided treatment in his paper, but he regarded viburnum with favor. He thought congestion of the uterus more important as a factor in abortion than retroflexion. He admitted the importance of chronic cardiac disease.

Another Remedy for Perspiring Feet.

The *Medical Press*, January 21, 1891, says that Dr. Winogradoff recommends a 5 to 8 per cent. solution of chloride of zinc as an application for the prevention of undue prespiration of the feet. He begins by ordering the feet to be well washed in tepid water, and then dabs on the solution, wiping off the surplus a few minutes later. The application is best made at night, and may require to be repeated a week later. It acts as a caustic, destroying the sudoriparous glands, and should never be used except by the medical man himself.

NEWS.

—It was reported from Odessa, Feb. 2, that a hospital at Skopin has been destroyed by fire, fourteen patients perishing in the flames.

—A young Englishman named Bosanquet, was bitten by a rattlesnake, at Daytona, Florida, on February 1 and died the next day in great agony.

—On February 3, Dr. John S. Billings was chosen by the Trustees of the University of Pennsylvania Director *pro tem.* of the new Department of Hygiene, and Dr. A. C. Abbott, of Johns Hopkins University, first assistant in the department.

—Dr. C. C. Lancaster, a leading physician of Knoxville, Tennessee, died, February 3, of blood poisoning. He was inoculated with the septic matter a few days ago, while performing an operation on a body having a gangrenous wound.

—An amendment to the State Pharmaceutical law of Pennsylvania, giving graduates in pharmacy the privilege of registering without examination before a Pharmaceutical Board, was favored at a recent meeting of druggists in Philadelphia.

—A despatch from New Haven, Connecticut, Feb. 6, says that a girl about 10 years old, of Shelton, had been hiccoughing incessantly for six weeks, and nothing had afforded her any relief. She was wasted to a skeleton, and death was but a question of a very few days.

—Dr. J. D. Nicholson, resident physician of the Cooper Hospital, Camden, N. J., has resigned to accept a position in the Philadelphia Hospital. Dr. I. D. Webster, who was the junior resident physician, succeeds him, and the Board of Managers has appointed Dr. Farrar, of Virginia, to fill the vacancy.

—Clarence W. Bowen, Secretary of the Committee on the Cenntennial of Washington's Inauguration, 251 Broadway, New York, desires information regarding the portraits of Thomas Fitzsimons, Thomas Hartley and Thomas Scott, members of Congress from Pennsylvania. These portraits, for the Memorial Volume, are particularly desired, to complete the list of portraits of the Pennsylvania delegation in Congress at the time of Washington's Inauguration.

—Dr. Benjamin Lee, Secretary of the State Board of Health of Pennsylvania, has accepted the position of Secretary of the Section on State Medicine of the American Medical Association. As the meeting takes place in Washington, May 5, it is important that all papers intended for this Section should be in his hands by the fifth of April. All members of the Association desiring to be enrolled in the Section are requested to forward him their names at 1532 Pine St., Philadelphia.

OBITUARY.

TROY S. SAUNDERS, M. D.

Dr. Troy S. Saunders, who has long been a subscriber to the MEDICAL AND SURGICAL REPORTER, died Jan. 20, 1891, at Indian Springs, Ga., of acute pneumonia. He was graduated at the University of Nashville in 1867. He was unmarried, and was nearly forty-seven years old. He was a noble, good man, and sacrificed his life to the profession he loved. Many people—mostly poor ones—black and white, have been sick with the prevailing colds and coughs. He ministered to their wants, when he should have been in bed. This tribute is paid him by a life-long friend. J. V.

WILLIAM R. WARNER & CO.'S

PIL. CHALYBEATE COMP.

IN THE TREATMENT OF

LA GRIPPE.

FORMULA:—Carb. Protoxide of Iron, gr. ijss.
Ext. Nux. Vom., ... gr. ⅛

ADVANTAGES:—Does not constipate, is easily absorbed, is nerve tonic and quickly soluble.

The effects left by La Grippe are marked Physical Prostration for which Pill Chalybeate Comp. (Warner & Co.'s) is almost a specific. The assimilable iron, acting as a blood tonic and the Nux Vomica as a stimulant to the spinal cord.

Dose, begin with one pill every four hours and increase to two pills three times a day.

The acute symptoms of La Grippe are controlled by (**EFF. ANTALGIC SALINE**), one dessert spoonful of which contains 4 grains Antipyrine and 4 grains Salicylate Soda. Physicians will not be disappointed in the treatment of La Grippe by trying this salt followed by PILL CHALYBEATE COMP. as above mentioned.

WILLIAM R. WARNER & CO.,

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

MEASLES, WITH NOTES OF OBSERVATIONS.

BY A. F. MYERS, M. D.,

BLOOMING GLEN, PA.

Within the past year an epidemic of measles occurred in this community, and considering the number of years since a similar epidemic took place, one will not be surprised to find a great variety of cases, old and young, and with various complications and idiosyncrasies. In February, 1890, they made their appearance in our public schools, a regular hot-bed for propagation, and consequent depopulation. In less than three weeks forty individuals were affected by this troublesome affliction, and either high or low in station, they had to succumb, unless they had paid tribute to a former epidemic.

During the prevalence of this contagious exanthem, I took note of, and either directed or prescribed for 153 consecutive cases in private practice, of either a mild or more severe nature.

Invasion.—The onset of these cases was usually slow, with catarrhal symptoms preceding the fever. The characteristic early symptoms of the disease were intense nasal, pharyngeal and laryngeal catarrh, coryza, troublesome cough, occasionally violent headache and epistaxis, muscular soreness and irregular chills. Over one-third of the patients were distressed with an insatiable thirst. Redness and irritation of the conjunctiva and lachrymation was very distinct in over half of the number for a day, and in a few for even four and five days before any other signs or elevation of temperature became manifest. Many patients had a very moderate fever; however, using the clinical thermometer with every case noted, not a single one occurred where fever was entirely absent, though it has been claimed by some observers that such cases frequently exist. The fever usually came on by the third, and in a few cases as late as the fifth day after the prodromic signs were noticed, followed by remissions, on the appearance of the eruption of a crimson color in the face and spreading over the body. The fever lasted from one to six days—with a few exceptions to the seventh and ninth, attaining its highest point in nearly every case at the fullest development of the eruption. Marked enlargement of the anterior cervical and sub-maxillary glands was noticed in twelve cases during this period.

Temperature.—The range of temperature was a matter of interest. Of the 153 cases observed, in 115 it did not rise higher than 103°; of this number only 14 did not reach 100°. Seven cases ranged at 103°, and in three families numbering 7, 6, and 8 patients respectively, together with 5 isolated cases, it extended to 104° and a fraction; and in three exceptional cases it rose to 105°, and in one to 105.5°. However alarming it seemed, all these patients who had such a high fever—and where other complications contributed largely to this dangerous rate—finally recovered.

Eruption.—In the eruption nothing unusual was noticed. However, having made this epidemic a special object of observation, I found 22 cases where I was enabled to recognize distinctly the approach of measles by a peculiar rose-colored punctation of the soft palate, the uvula, and the roof of the mouth, from eighteen to thirty hours before the rash made its appearance elsewhere.

Incubation.—The exact period of incubation I could not determine; but in 21 cases that were under personal observation three times a day, and in which I carefully noted the time from the exposure until the appearance of the eruption, it was at the thirteenth day in 17 patients. In one case it was dis-

tinctly noticed on the ninth, in two on the tenth, and one on the nineteenth day.

Sex.—The sex was noted in every case, and I found there were more females affected than males. There were 82 of the former and 71 of the latter. This proportion of the sexes is in harmony, however, with the ratio of the entire population of this community.

Age.—It will be noticed that the disease was most frequent between the ages of 6 and 10 years, higher than is generally found; but this may be accounted for by the fact that no similar epidemic had taken place for a number of years. My observations were as follows:

No cases under 7 months of age.					
6	between	7	and	12	months,
19	"	1	"	3	years.
33	"	3	"	6	"
47	"	6	"	10	"
24	"	10	"	15	"
18	"	15	"	20	"
4	"	20	"	25	"
1	at	28	years.		
1	at	35	"		

Complications.—Of the complications that usually exist with or succeed this disease, the following will be briefly noted. Of the entire number, 128 were simple cases, and 27 complicated. The complications were: bronchitis, 16; convulsions—all in the early stage of disease—4; laryngitis, 3; pneumonia, 4; dysentery, 1; entero-colitis, 1; acute Bright's disease, 1; stomatitis, 2; otalgia, 1.

In this enumeration several cases are referred to twice. In no case was measles conjoined with any other eruptive disease.

Prognosis.—The prognosis was favorable in all the simple cases, every patient regaining the former excellent health. Of the 153 cases noted, only two terminated fatally. The unfavorable cases and the attending circumstances may be briefly stated.

Case 1. The first death occurred in a boy seventeen months old. The first signs of ill health were repeated convulsions for a half day. A brother having just recovered from this disease, it was surmised what was coming. I was called at this time and found the child having another spasm, continuing for over twenty minutes; the respirations were 40 to 43 per minute, the pulse-rate 135 to 140; the temperature in the axilla 105°; the child very restless; the skin hot and dry. The patient urinated frequently, but the urine was scanty. There was no appearance of an eruption. At short intervals during the intermission of the convulsions, the child would sit up and ask for water, and drink small quantities with an apparent relish. It answered questions and was evidently rational for a few minutes, when it would suddenly relapse into another fit. It continued in this manner during the following night. In the morning I found all the symptoms aggravated, continual convulsive movements, dyspnœa, 60 to 65 respirations a minute, and pulse fluctuating between 165 and 170 per minute. Bronchitis had developed during the night; and by mid-day a paroxysm of cough ended the scene. Permission for an autopsy had been refused.

Case 2. This patient was a girl eleven years old, with the eruption fully developed when I first saw her, complicated by an attack of catarrhal bronchitis. This patient had bad hygienic surroundings; the house was situated on a low, marshy bottom, with water in the cellar and the rooms very damp. As the eruption faded, catarrhal pneumonia set in, with a temperature fluctuating between 103° and 104.5°, rapid and laborious breathing, prolonged and noisy expirations, dry, painful cough, which had been loose during the bronchitis. Expectoration was now muco-purulent, the urine was scanty, and slight diarrhœa followed. In spite of all that I could do, this case proved fatal on the fifth day from the time that I first saw it.

Sequelæ.—All the patients have been under observation since their illness, and all fully recovered promptly, with the exception of the case complicated with otalgia, which became protracted, but by persistent attention for over a month, the inflammation in the middle ear disappeared, with hearing fully restored.

Treatment.—I will simply state that no routine treatment was followed, nor, in all cases, the advice usually given. I claim nothing original or novel in my procedure. The extensive administration of cold water and the various uses made of it for reducing the temperature and bringing out the eruption, is my excuse for bringing this subject to the attention of the profession.

In the management of this disease strict attention was given to the hygienic surroundings of the patient as much as the various inconveniences would permit. With a few exceptional cases this condition was very favorable. The temperature of the rooms was maintained as near as possible between 65° and 75° continually, to avoid overheat-

ing as well as chilling the body. The sick chamber was properly ventilated and shaded from bright light, to afford comfort to the eyes. Of the 122 cases having the simple form, 13 were not confined to the bed, but, being well clothed, were allowed the freedom of the room. The rest were comfortably covered in bed. Amusement was permitted in the simple cases if desired.

During the febrile period light diet was ordered, consisting of water and milk, crackers, or bread soup and tapioca. Later, as the eruption disappeared, light broths, toasts, soups and oranges were allowed. The drinks consisted of cold water, in abundance but in small quantities and frequently given. I gave cold water freely to allay the insatiable thirst; even iced water was exhibited in several cases, but in frequent small portions. Cold lemonade, orangeade and other cooling drinks were allowed *ad libitum*. To give very large draughts of cold water at once is injurious; it will frequently cause violent gastric pain and vomiting, followed by other unpleasant symptoms.

Where the temperature was very high, the skin dry and hot, and the patient often suffering from fever-pains, with a tardy appearance of the eruption, a careful sponging with cold water was very agreeable and highly beneficial, followed by a gentle rubbing with a dry towel. After it was once tried, the patients frequently solicited its repetition. In several cases where friends protested, I used only tepid water, with good results. The reduction of temperature was phenomenal in some cases. Using the thermometer, I noted four cases where it declined two degrees in one hour's time. In three cases where the eruption was tardy and there was high fever, a warm bath for about twenty minutes also accomplished our design. In no case did any unpleasant symptoms follow.

Diaphoresis, and the action of the kidneys, was carefully looked after. No patient was permitted to suffer, however, for the want of the proper medicinal treatment if indicated. No partiality was shown to any means or method.

In eighteen cases of high fever, I applied ice to the head for a few minutes at frequent intervals, by means of an ice-bag, to relieve the throbbing pains. Three cases of convulsions, in the early stage of the disease, were treated similarly together with a warm bath, until the convulsions ceased, with gratifying results.

In the fatal case of the boy cited above, much to my regret, neither of these plans was made use of.

The account of the medical treatment will be abbreviated. Of the simple form, 76 cases received no medicinal treatment except syrup mixtures of wild-cherry, scilla or ipecacuanha, for the relief of the incessant, dry, scraping cough, in such proportion as was indicated. For constipation, in the more severe cases, I prescribed an emulsion of castor oil or spiced syrup of rhubarb, according to age. As a diaphoretic, sweet spirits of nitre was used in twenty-four cases; and to control the diarrhœa, bismuth subnitrate and Dover's powder, or a few doses of camphorated tincture of opium as necessary. For six cases of high febrile reaction, citrate of potash, spirits of nitre and tincture of aconite was administered. For the conjunctival inflammation, a warm-water lotion was frequently used. The local use of vaseline afforded great relief where pruritus existed during the decline of the eruption, or where any desquamation followed.

The remarks on the treatment of the complications will be brief. Absolute rest and quiet was enforced in this class of cases as long as was deemed necessary. Bronchitis was from the onset treated with supporting measures. The diet was of the most nutritious sort; febrifuges, expectorants and external applications were used as indicated. The cases of pneumonia were treated according to the general principles given in the text-books. From the other complications, all recovered under the common treatment in vogue for such diseases. Only six patients required tonic treatment for a week, as a result of the complications.

TREATMENT OF DYSENTERY.[1]

BY D. H. BERGEY, M. D.,
NORTH WALES, PA.

During the month of July I had a number of cases which so closely resembled dysentery that, for want of a more appropriate term, I called them by that name; yet in severity, and possibly in the course of the disease, they differed somewhat from dysentery. I also experienced some difficulty in giving relief to several of these patients

[1] Read before the Montgomery County Medical Society, September 24, 1890.

by the use of the ordinary remedies. This difficulty led me to make use of a combination of agents which gave me good results, and has given equally good results in undoubted cases of dysentery since, and has led me to change my views with regard to this disease.

We are taught to regard dysentery as being primarily an acute inflammation involving the mucous membrane of the large intestine, which various authorities have attempted to trace to a bacterial origin. This theory I consider fallacious, because the micro-organisms so far found in the dejections in this disease have all been frequently found in the mouth of healthy persons where their presence was not accompanied by any pathological conditions. The bacterial origin has been exploded, unless we recognize that of Kartulis, which recently received some confirmation through Prof. Osler. Yet even these organisms, the *Amœbæ Coli*, are denied this distinction by Baumgarten.

I consider the causative element in dysentery to be an arrest of the secretion of bile, and possibly also of the pancreatic juice. I think you will grant that this theory is not unfounded, when you consider the absence of the characteristic odor and color of the dejections in dysentery. This color and odor we know to be due to the bile and to certain elements resulting from intestinal digestion.

The absence of these two characteristics in the dejections in dysentery is the most prominent diagnostic point; even more so than the presence of mucus and blood; and in the treatment of this disease the return of the natural coloration and odor of the feces, and hence the presence in them of bile constituents and the products of intestinal digestion, is the first indication that convalescence is being established.

In the cases of which I have spoken I tried ipecacuanha according to the Brazilian method of treatment, without obtaining very gratifying results. The salicylate and the subnitrate of bismuth, either alone or in combination with Dover's powder or opium, had no effect. Salines were tried in several cases without avail. Repeated doses of castor oil and laudanum gave partial relief in some of the cases where tried. Minute doses of calomel had little effect. These unsatisfactory results led me to employ an elixir, the principal agents in which were ox-gall and pancreatine. The absence of the natural coloration and odor of the feces led me to believe that the disease must have some connection with the functions of the organs furnishing these secretions; and I was led to supply their secretions artificially. The results were very gratifying. In from twelve to twenty-four hours the characteristics, which were absent heretofore, returned and the tenesmus abated, and mucus and blood were no longer present in the dejections.

I am led to believe that dysentery is due, primarily, to an arrest of the secretions of the liver and pancreas, which allows putrefactive changes to take place in the intestines, and that these putrefactive elements are the sole cause of the inflammation. The lesions, it seems to me, may be looked upon as the result of the fermentation going on, because of the absence of bile, the normal antiseptic; the lesions prolonging the disease and offering a habitat for the bacteria.

This condition, therefore, calls for antiseptic treatment, and we fortunately have, as proven by Limbourg, an efficient antiseptic in the biliary elements contained in the ox-gall, which takes the place of those secretions temporarily absent. Bile is also the best cholagogue. That it is cathartic in its action, is shown at once by the diarrhœa which accompanies excessive secretion of it, by the constipation which is ordinarily present in congestion of the liver; and by the purgative properties of ox-gall when given in sufficient doses. It seems to produce its purgative action by stimulating the secretion of the intestinal and pancreatic juices and by increasing the peristaltic action of the intestines.

In pancreatine, we have an active agent bringing about the natural decomposition of the chyme, thus rendering it rapidly assimilable; it therefore is a most important agent in the restoration of the natural functions of the liver and of the organs of assimilation, and therefore of the entire economy. The presence of fatty particles in the dejections of this disease shows the absence of the pancreatic secretion, since it is its office to emulsify fats in the presence of bile. These two agents are assuredly those whose absence allows the putrefactive changes to take place in the intestines and thereby brings about such violent attacks of inflammation of the mucous membrane of the large intestine, with its concomitant constitutional conditions—fever and prostration. It seems to me more than probable,

therefore, that the violent inflammation, at least in the simple form of this disease, is due altogether to an irritation set up by these putrefactive elements and that the disease is due primarily to an arrest of secretion in these two organs.

To further substantiate this conclusion, I may mention the fact that we have a gastro-intestinal catarrh accompanying cirrhosis of the liver, and here we have at least a partial arrest of the secretion of bile; while, when there are cysts of the pancreas, we have fatty matters in the dejections, colic-like pains, and frequently bloody stools. When, as in dysentery, the secretion of both of these organs is checked simultaneously and suddenly, as it is possible for it to be, by continued high temperature followed by cold and dampness, or by whatever cause, it is not necessary to stretch our imagination very much to picture the resulting conditions. There is really a constipation existing at the time, the dejections being composed largely of mucus and blood from the large intestine alone. The tormina and tenesmus may be looked upon as largely due to ineffectual efforts on the part of nature to unload the bowels.

We have thus far experienced considerable disappointment in the treatment of dysentery, and it seems proper to conclude that this disappointment has been due to the fact that the true causes leading to this affection have been overlooked. I believe that when we come to regard this condition in its true light we shall meet with far more gratifying results.

In the majority of cases it is preferable to preface the treatment of dysentery with a large dose of ox-gall, or other cathartic, as castor oil, to unload the bowels. When this is done, my experience leads me to predict that from twelve to twenty-four hours' treatment with ox-gall and pancreatine will suffice to re-establish the normal secretions, and to establish convalescence.

Should the tormina and tenesmus continue after the dejections assume their normal color and odor, a few injections of bichloride solution with starch-water will be followed by almost immediate relief.

This has been my experience with acute dysentery during the present season. Though it may seem fanciful to some of you, I trust you will not hesitate to try this mode of treatment in dysentery.

I have given both of these agents together in pill form and in the form of an elixir, from one-half to one grain of the ox-gall and from seven to fifteen grains of the pancreatine, every three to six hours. I have also given the ox-gall alone, in pill form and in capsules, and the pancreatine in the form of a simple elixir.

MEDICAL TREATMENT OF PERITONITIS.[1]

BY W. S. WASHINGTON, M. D.,

NEWARK, N. J.

Peritonitis was not raised to the dignity of a disease until about the beginning of the present century, and during that time its treatment has undergone many variations.

The earliest authors give copious general and local depletion, and mercurials, as the treatment. Some of them, however, used purgation, though it does not seem to have been at all popular, and we only occasionally read of it.

We find no mention of opium until about 1820. From that time till 1830, Graves and Stokes used it in large doses in perforative peritonitis, but no mention is made of its use in other forms of the disease. Sir Thomas Watson, in his classical lectures delivered in London, speaks of the profound impression made upon his mind by these reports. He himself gives rest, venesection and opium as the three main remedies to be relied on. Sir Thomas disapproved of purgatives. Dr. Alonzo Clark, about 1840, was the first to begin the systematic use of large doses of opium in all forms of peritonitis. He put his patients in a condition of semi-narcotism and kept them in that condition until the inflammation subsided. It is inconceivable, however, that the enormous amounts administered could all have been absorbed. No purgatives were allowed, and the bowels were kept confined as long as two weeks if necessary.

Dr. Austin Flint advised much the same plan of treatment, especially disapproving of purgation. Dr. George B. Wood, in the fourth edition of his work on *Medicine*, published in 1855, gives copious bleeding as the most important remedy; then came five or six grains of calomel, followed by castor oil or Epsom salts. Next in order was from fifty to one hundred and fifty American leeches, followed by opium and mercury to ptyalism.

[1] Read at the meeting of the Practitioners' Club.

While Dr. Wood deprecated anything which tended, as he thought, to produce continued friction of the inflamed serous surfaces of the intestinal convolutions, he deemed it proper to procure one or two soft evacuations daily by the use of Seidlitz powders, Epsom salts, Rochelle salts, infusion of tamarinds with cream of tartar, castor oil, or castor oil with oil of turpentine. Dr. Wood did not advise or use large doses of opium. Bauer, in Ziemssen's *Cyclopædia*, recommends ice in the outset, to withdraw heat and allay pain. He believes cold lessens the hyperemia, reduces nervous irritability and spasmodic peristaltic action. As soon as the muscular action of the intestines and blood-vessels is paralyzed by distention and pressure, the ice is exchanged for heat. The next remedy, according to him, is opium. He says the use of cathartics is completely given up. For the relief of tympanites, the rectal tube and puncture of the colon are employed, though both are admitted to be of very limited value. Wardell, in Reynold's *System of Medicine*, says our best ally is blood-letting. Then come leeches, hot fomentations and opium. Purgation means increased irritation. Dr. Henry Hartshorne, of Philadelphia, entirely agrees with Wardell. Dr. Ross, in the *Reference Hand-book of the Medical Sciences*, after speaking of local depletion, says opium is the drug most relied on, and that it should be given in full doses. The bowels should not be disturbed by cathartics or enemata until all active symptoms have subsided. Bartholow recommends leeches, the ice-bag until there is exudation, then heat, and morphia and atropia hypodermically.

Other authors have advocated similar treatment. Of course other remedial measures were used as adjuvants, but the foregoing represents the principal methods of treatment used until the last few years. I believe we are indebted to the gynecologists for a system now advocated by a large number of medical gentlemen, and known more distinctively as the purgative treatment. Under this method active purgation is employed and opium is used as little as possible or not at all. Pain and tympanites are two distressing symptoms of peritonitis. Opium will relieve pain but not tympanites. Purgatives, more especially saline purgatives, will relieve both. Epsom salts, which I prefer, does not act by increasing the peristaltic action of the intestines, but it produces a watery movement by osmosis from the blood-vessels of the peritoneum and intestines. That it does increase the amount of water in the intestinal canal has been proved by placing a solution of magnesium sulphate in a knuckle of intestine. On examination made some time afterwards an augmented quantity of fluid was found.

Among those who speak of the use of purgatives with approval is Lawson Tait, of Birmingham. He was among the first, if not actually the first, to use them, and his preference is for salines.

Dr. Nancrede, professor of surgery at Ann Arbor, Michigan, advises the use of salines in the peritonitis preceding and following appendicitis. Dr. Gordon, of Portland, Maine, in a report of a number of cases of peritonitis of various kinds in women, says: "I think the first and most important therapeutical resource is free catharsis from salines, preceded sometimes by the calomel triturates, if the stomach is irritable. If these fail to act promptly, I supplement by an enema of a concentrated solution of Epsom salts. I find the following formula effective: Magnesia sulphate, ℥ij; boiling water, f℥iij; glycerine, f℥i. It acts promptly and thoroughly, stimulating the entire intestinal canal, producing profuse watery discharges, and rapidly reducing temperature and relieving pain. Opium should be withheld unless the pain is intolerable. The enema alone often completely aborts the attack."

Dr. A. M. Jacobus, instructor in gynecology in the New York Polyclinic, says: "Peritonitis, even the so-called idiopathic form, if there be such a thing, is necessarily a serious disease; but when the patient has not only to fight it, but the non-operating opium poisoner, it means certain death in a large percentage of cases. Opium has had its day as a cure-all, and it seems now only a question of what kind of a laxative we shall use. I have seen several instances of general and pelvic peritonitis in which it appeared certain that without free catharsis the patient would have died from cardiac or respiratory paralysis, from the excessive tympanites or from septicemia in purulent cases. In several instances of obstructive peritonitis, when Seidlitz powders failed and there was excessive tympanites, an ounce of castor oil in hot milk saved the patient from certain death. We use cathartics in the inflammatory intestinal diseases of infants, and in general inflammations elsewhere as revulsives, then why not in peritonitis with effu-

sion, whether septic or not? Whether in operative cases or not opiates should be used as little as possible; but, on the other hand, saline or vegetable cathartics, followed by enemata should be used from time to time to relieve the inflammation, tympanites, pains and fever, and especially to drain the peritoneal cavity of serous or purulent effusions." Dr. W. Gill Wylie, of New York, advises and uses cathartics in peritonitis, preceding and following laparotomy for various causes. Dr. Baldy, of Philadelphia, expresses himself as follows on this subject: "The peritoneal cavity is drained of the products of inflammation; the inflamed surfaces are relieved of all engorgement by a thorough depletion of the vessels in the intestinal walls; the inflammation is most effectually stopped; the pulse and temperature almost immediately improve; and the pain is relieved as quickly as can be by the use of opium. This may seem strange, but it is a clinical fact."

Dr. John H. Musser, Assistant Professor of Clinical Medicine in the University of Pennsylvania, has reported over twenty cases of various forms of peritonitis, many of them very severe, treated after the following method. Local blood-letting, until pain is very much relieved. If in progress more than forty-eight hours, a large blister, followed by hot applications; liquid diet absolutely; stimulants to prevent collapse, to lessen its severity and to prevent tympany; sips of hot water or hot whiskey and water for vomiting; calomel in small doses hourly until the bowels are moved, and if no relief is obtained it is pushed to ptyalism. If the patient is seen early, aconite is given to children, veratrum viride to adults, until the pulse-rate is lessened. Morphia and atropia are given in small doses as infrequently as possible to control pain; twice daily often suffices. If morphia disagrees, codeia is to take its place. If the bowels are not opened in forty-eight hours, one pint of sweet oil is given by enema, followed by an enema of tepid water. Dr. Musser considers it of the utmost importance that the bowels should be opened. In threatened collapse, active stimulating medication is employed by subcutaneous injections. It will be observed that Dr. Musser employs local depletion, calomel, blisters, etc., which are not new, but at the same time it will be noted that he reduces opium to the smallest possible amount. Although in this summary of his treatment no mention is made of salines, yet in the detailed report of cases, one is recorded as having been relieved by them. The treatment of these cases by Dr. Musser was eminently successful.

Dr. Emory Lanphear, editor of the *Kansas City Medical Index*, gives his unqualified support to the saline purgative treatment, and reports a number of cases, some of which were treated by opium and others by salines. The results were startlingly in favor of the latter. Dr. Maxson, of Hartford, Kansas, Dr. Lanphear's preceptor, has treated peritonitis by salines for the past twenty years. He believes they unload the turgid blood-vessels and relieve the impeded circulation of the abdominal viscera and peritoneum; that temperature and pulse rapidly lessen in frequency; and that pain disappears almost as quickly as by the use of opium. In the second stage, he uses small doses of salines with tincture of belladonna and a limited amount of opium to relieve pain, sustain the heart and prevent shock.

In the past three years a large number of gentlemen have reported cases and testified their faith in the new method. It seems to have gained a secure footing, and it will eventually displace the old opium treatment. I entirely agree with the views of the different ones I have quoted in its favor, and can confidently recommend it to those who have not as yet had experience with it. In closing, I will report the following cases.

Case 1. One of general peritonitis. The immediate cause was sitting on cold doorsteps in front of a boarding-house late at night; the remote cause was a previous peritonitis. The patient, a woman, was of a bilious habit, and had much nausea during the whole of her sickness, which was relieved by calomel. Saline purgatives, in the form of magnesia sulphate, promptly relieved pain and tympanites, being used as often as required. Sometimes they would be given daily, at other times an enema took their place. Turpentine stupes were applied to the abdomen and liquid diet was given. One-eighth grain of morphia was administered as required; on some days none was given, on other days two or three doses would be given. The woman made a perfect recovery, and after the first three or four days was not considered dangerously sick.

Case 2. One of local peritonitis accompanying salpingitis. The patient was promptly relieved by purges of magnesia sulphate. The deodorized tincture of opium was given for pain and flannels wrung out

of hot water were applied to the abdomen. Very little opium was required or given, and recovery was satisfactory.

Case 3. One of local peritonitis following child-birth. Magnesia sulphate relieved immediately, and but one dose of one-eighth grain of morphia was needed. Although puerperal mania developed within a few days, the peritonitis disappeared without further trouble.

CYSTOMA OF JAW.

BY THOMAS H. MOORE, D. D. S., M. D.,
PHILADELPHIA

Mr. I., 46 years old, presented himself at my office, having a tumor involving the left half of the inferior maxilla. The growth, he says, began several months prior to his coming for treatment, and had attained considerable proportions. The cyst extended from the angle of the jaw almost to the median line at the symphysis. The swelling was first noticed upon the lingual portion of the jaw, opposite the second inferior molar. It gradually increased in size, and then made its appearance upon the buccal surface and extended anteriorly and posteriorly, involving nearly the whole left half of the jaw.

No reasonable doubt can be entertained but that the teeth are, in most cases, the primary cause of such mischief. But the question of the precise manner in which the morbid conditions are developed is more difficult of solution. There is no disputing the fact that foreign bodies, such as the apices of teeth, broken off during extraction, or small spiculæ of bone, attracting a serous fluid around them, finally become encapsulated or encysted and gradually extend to great proportions.

Cystic tumors of the inferior maxilla are by no means of common occurrence, and present especial features, such as slowness of growth, absence of severe pain, glandular involvement, or constitutional impairment, except such as attends any tumor interfering with mastication or deglutition. The manner of discovering their true nature is by the aid of the exploring needle. In the present case I wish to say that the patient, being possessed with a very fine set of natural teeth, none of them being devitalized, imagined they could be used for almost any purpose other than that for which they were intended. He placed a hard shellbark between the two second molars of the left side of the jaw, and cracked it. Immediately after he experienced a slight pain in the lower tooth. This was evidently the cause of the formation of the tumor. The excessive pressure upon the cancellated bone injured the endostium, producing an effusion, and that is what formed the nucleus for an extended, but slow, inflammatory action, with the consequent results

Obviously, there is but one sort of treatment for these tumors, and that is surgical. When they have not extended or reached to such proportions as to completely destroy the contour of the bone, I make a free incision, to evacuate the contents. In the case being described this consisted of a dirty, bran-like substance, mingled with a glairy, blood-stained fluid. I made a further examination with the exploring needle, and discovered another but smaller cyst posterior to the one just opened, and having its connection by a small sinus opening into the first one. I evacuated its contents also, and proceeded to wash out the cysts with tepid water. I then injected a stimulating solution of dilute tincture of iodine, and packed the cavity with gauze, which I renewed, repeating the injection of dilute iodine for a few days, until complete closure was accomplished. No internal medication was required in this case.

REPORTS OF CLINICS.

BUFFALO GENERAL HOSPITAL.

SURGICAL CLINIC—PROF. ROSWELL PARK.

Tubercular Gumma, breaking down into Cold Abscess.

Dr. Park said the patient, a young compositor, asserted that two years ago a swelling had occurred on his wrist without much pain or redness of the skin. After applications of iodine, vigorous handling, etc., it enlarged. A year ago he noticed a thickening and softening of the palm of the hand with a peculiar sensation. When he pressed in the middle of the hand there was a bulging of the tumor above the wrist. This phenomenon persisted about six months. The swelling of the wrist is about 2½ inches in diameter, considerably elevated, with a red-

dened surface, and looking very much as if there was an acute abscess, but without heat and with no particular pain; so that the idea of acute abscess can be dismissed. The boy is more or less emaciated and, in time past, he has been worse than at present. He has a cough and looks phthisical. He is not a type of the scrofulous diathesis, and probably is not phthisical at present; though he is on the point of becoming so. The trouble about the wrist may be cold abscess, that is, tubercular abscess, or a tuberculous or syphilitic gumma—new formations of the type of infectious granuloma—or a cystic or solid tumor. Leprosy need not be considered in this part of the country. There is no history of syphilis. It cannot be a malignant tumor; for if it were it would have spread more in the last two years, and it would have become firmly seated and immovable, through the contraction of adhesions to surrounding parts. The patient can move his fingers freely.

A cyst or lipoma would fluctuate as this swelling does, but the skin over them would not be red. A fibroma would be firm and hard, and it, too, would not be covered by a reddened skin, unless it were on the point of ulcerating. The diagnosis is narrowed down to tubercular trouble—either a gumma or a gumma broken down into a cold abscess. It probably began in the cellular tissue between the skin and the deeper parts, and it has probably formed adhesions to the sheathes of the flexor tendons. The exposure of the tendons is a serious thing because the new formed cicatricial tissue will lash the tendons down.

A synovial sheath filled with fluid is called a hygroma, and this is the condition in the palm. Sometimes a hygroma contains not only fluid but little solid masses apparently due to precipitation from the fluid. A hygroma may be considered a special form of "cysts by distention of previously existing cavities." The solid bodies may be of the size of millet seeds or even as large as beans. The average size is about that of a grain of rice, and they are often called rice-grain bodies. Very little is certainly known of them. They consist almost entirely of fibrin and are probably formed by the rolling into masses of fibrinous matter in the hygroma. This condition is probably quite independent of the tubercular gumma of the wrist.

Dr. Park then laid open the tumor on the wrist and considerable fluid and puruloid matter and masses of coagulated lymph were evacuated. The pyogenic—or, as Dr. Park prefers to call it, the *pyophylactic*—membrane was peeled off, preserving its sacculated appearance. The curette was then used. Both during the operation and during the dressing, rigid antisepsis was carried out. Sometime before the operation the wrist was shaved and scrubbed and enveloped in an antiseptic bandage.

New York Correspondence.

MEETING OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

President's Opening Address: Medical Examiners.—Cystoscopy.—Holt's Divulsor.—Sarcoma in Brain.—Discussion on Refraction.—Appendicitis.—President's Annual Address: Education of Girls.—Experiments with Koch's Lymph.—Gynecology.—Electrical Treatment.—Election of a President.

The eighty-fifth annual meeting was held in Albany, February 3, 4 and 5, 1891, with Dr. W. W. Potter, of Buffalo, as President. This meeting was, as usual, well attended by delegates from all parts of the State and by invited guests.

The President, in the course of his opening address, congratulated the Society that the State was now near the realization of its long-desired deliverance from the thraldom of a system which had, more than all other causes, retarded the progress of medicine. A State medical examining Board would come into power this year. The right to grant medical diplomas was now divorced from that of the license to practice. The medical colleges were all bound by the provisions of the new law to give three full courses of medical instruction in different years before granting diplomas, since candidates would not be admitted to the examination for license with less preparation. It was more than possible that the effort would be made to weaken the law by amendment, or to have it repealed. He urged that the law as it now stood should be accepted loyally. If, on due trial, it should be found to contain defects they could be remedied as experience showed their existence.

Dr. Willy Meyer, of New York, in a

paper on the progress of cystoscopy in the last three years, gave the histories of some very interesting examples of the great advantages which had been derived from the use of this instrument in determining many points, by actual observation, of the processes going on within the bladder which proved of signal service in the indication for treatment. The author had demonstrated to his own satisfaction that cystoscopy was an easy and harmless examination, but that its successful employment required experience. In all kidney or bladder disease it might be practiced repeatedly if necessary, before operative interference for diagnostic purposes was undertaken. It should be performed as a *dernier ressort* after all other known means for making a diagnosis had been exhausted. If properly applied cystoscopy would clear up uncertainty in an obscure disease of the bladder. In most cases we could determine with the help of electric illumination of the bladder whether we had to deal with disease of the bladder or of one of the kidneys. We should soon be able with the instruments now in process of perfection to catheterize the ureters and gather the urine from each kidney separately. These facts would tend to make superfluous a preliminary section or a perineal invasion for diagnostic purposes.

Dr. F. R. Sturgis, of New York, made a plea for the advantages which he contended the Holt's operation by divulsion of the urethral strictures possessed over internal urethrotomy. It was well known that even fatal hemorrhages occurred as a sequel to the latter method. Since adopting rapid dilatation he had never had an instance of hemorrhage uncontrollable by cold or septic injections. By Holt's method the occurrence of severe chills was avoided, in fact he now deemed it unnecessary to take precautions against this accident. Septic complications he had never known as the direct result of rapid divulsion.

Dr. D. Lewis said he had got quite accustomed to patients coming to him from the urethral operator with their boots full of blood, and then it took as long to get them into shape as it would have done to cure the stricture by gradual dilatation.

Dr. L. C. Gray narrated an interesting case of paralysis of the motor and muscular senses involving the upper and lower extremity of one side, in which the symptoms had been rapidly developed and in which a diagnosis had been made of tumor of the centrum ovale. At the autopsy a round-cell sarcoma about the size of a hickory nut was found about one-fourth of an inch beneath the cortex at the junction of the leg and arm centre of the posterior central convolution. Dr. Gray considered this case unique in view of the rapid growth of the lesion, as indicating the exact localization of the muscular sense.

Dr. St. John Roosa, in a paper on the causes of asthenopia, denied the existence of a perfectly normal refraction. The emmetropic eye was not known in the human race, unless as a rarity. It was absurd to attempt the cure of asthenopia by tenotomies upon the ocular muscles. All the causes of this condition, excepting in those cases which were congenital and resulted from irregularities in the development of various diameters of the eyeball, were to be looked for in abnormal states of the nervous system.

Dr. Noyes emphatically opposed this view and believed that muscular insufficiencies might often be found and treated by prisms or operation and the existing asthenopia thereby benefited or cured.

An entire session was devoted to the subject of appendicitis. Dr. C. McBurney said that clearly-defined rules as to when a case of appendicitis might be left to medical treatment alone could not be laid down. It might be laid down as a rule with but few exceptions that the indications for advancing disease could be clearly made out by the end of thirty-six hours, if an early diagnosis had been made and this had been followed up by subsequent careful examinations. Significant symptoms at this period offered the necessary indications for operation.

Dr. Robert F. Weir said he had been obliged to modify his opinion of a year ago. He now believed that intermediate laparotomy or operation in the quiescent stage in recurrent cases might be done where the patients were debarred from the enjoyment of life or the ability to earn a living.

Dr. A. Vanderveer, of Albany, considered that the care of cases of appendicitis, so far as the physician was concerned, consisted in an early diagnosis, and that then it became his duty promptly to share the responsibilities of the case with the operating surgeon until surgical interference had been decided upon or negatived.

The President, in his annual address, discussed the problem of the education of girls. In the course of his remarks he said that the sexual system was the pivotal part of wo-

man's organism, and when disordered or diseased the pernicious effects of such derangements pervaded her whole being. The reproductive organs were in ultimate relation with all the other organs, through the ganglionic system and with the brain through the cerebro-spinal system. At puberty and sometimes before, as well as after, the nervous element was dominant in the female economy, and these two systems, the sexual and nervous, acted and reacted upon each other with a complexity difficult to comprehend. Now if the nervous supply to the sexual system was received from an overtaxed and badly-nourished brain, it was but reasonable to anticipate disturbance of the functions of the latter. The essence of many of the diseases which afflicted young women lay, not in the reproductive organs in the beginning, but in faults incident to imperfect hygienic surroundings, faulty alimentation, overwork in study, and a variety of causes which operated banefully at a time when, by the predomination of the sexual sphere, the local expression of the fault was referred to the sexual system. He would have young girls taught the importance of eating good, plain, nutritious food, and above all, the necessity of eating a hearty breakfast. Too many young women had grown up to regard it as vulgar to indulge the appetite at the morning meal, and had been allowed to cultivate the habit of mincing and sipping at a few dainty dishes or had been permitted to go without breakfast altogether. It had been said that a woman's physical beauty was in direct proportion to the amount of beefsteak and mutton chops she could consume at this meal.

Elaborate reports were made in a series of carefully-prepared papers by a number of physicians, upon whom have devolved the initial experiments with Koch's lymph in New York and elsewhere.

It would be superfluous to go over the ground of evidence and information, the details of which are already graven upon the mind of every inquiring physician in the land. Expressed as a simple equation, it would appear that with the exception of lupus, and some cases of laryngeal tuberculosis, which are so far reported cured or greatly benefited, the lymph has failed as yet to realize the overwrought expectations which characterized its reception as a specific therapeutic agent. It was, however, calmly stated that the time had not come when a final opinion could be demanded, and that to the best of the belief of the various experimenters, the agent would yet prove as powerful, from a remedial point of view, as it was now shown to be in determining the existence of tuberculous tissue within the human organism. It was also conceded that to Koch would belong the honor of ushering before the medical profession a therapeutic principle pregnant with possibilities, the importance of which was beyond prophecy.

In the course of a long session devoted to the subject of gynecology Dr. McMurtry, of Louisville, stated that when a patient presented the history of recurrent attacks of pelvic inflammations it was at once indicative of leaky tubes. In such event the only treatment was by abdominal section. It was amazing to see with what reluctance the medical profession had come to accept this great advance in pelvic surgery. Even now, when masses of suppurating tubes and ovaries were dug out of the pelvis in the midst of virulent peritonitis, and the patients were saved from an hitherto fatal condition, many eminent members of the profession stigmatized the procedure as the castration of women. So far as he was aware surgeons operated upon the female pelvis for local disease only and never with the idea of affecting a cure of reflex disturbances and obscure symptoms.

In a discussion as to the value of electricity as a remedial agent in the treatment of uterine tumors Dr. Ross, of Toronto, expressed the opinion that electricity was fast losing its fashionable favor and that the battery was walking in the footsteps of the spray; still it might remain of use to the profession in a variety of ways. Dr. Gill Wylie thought that electricity as a destructive agent to the tissues of the tumors was practically of no influence. If used to stop hemorrhage it must be employed in such strength as to act as a cautery. It was important to avoid any form of treatment which would leave a scar in the uterine tissues, which would be liable to close up the glands and follicles, thus interfering with normal secretion and setting up a train of reflex symptoms. He considered the use of electricity as dangerous as that of operative procedures.

Dr. A. W. Suiter, of Herkimer, was elected President for the ensuing year.

—Picrotoxine, the active principle of cocculus indicus, is considered by Bokai as the best physiological antidote for morphine.

PERISCOPE.

The Koch Treatment in Vienna.

The correspondent of *The Lancet*, January 31, 1891, says: Koch's second publication has caused considerable surprise in medical circles, and especially the first passages of his paper in which all the publications made by clinical observers on the action of the remedy were ignored. Recollecting the statement of Minister von Gossler, that the preparation of the remedy could not be described (a unique statement in view of the great advancement of natural science), the physicians were somewhat astonished by the simplicity of the preparation of Koch's liquid, the more so as Koch was found to be following the directions initiated by Pasteur's school, and by the works of the late Dr. Wooldridge, Hankin and others, without mentioning even the names of his scientific predecessors. It must be assumed that Koch's second publication has not been less premature than his first one, and that it has been provoked by Virchow's reports. The effect of suggestion on the subjective symptoms in patients could not be better illustrated than in the recent era of Koch's treatment. At first it was rare to find a patient subjected to the cure who did not feel better at least in some way after the injections; but after Virchow's publication, which has been widely circulated by the lay press, the majority of patients in the General Hospital commenced to complain of different new subjective troubles which were ascribed by them to the action of the liquid, and there were frequently cases where the patients, formerly highly enthusiastic, declined to be treated further by Koch's method. Certainly the General Hospital, with its constant pressure of space, has not been a suitable place for such an extensive trial as has been made here at the clinics, where about 30 per cent. of the beds were alloted to tuberculosis and lupus cases—that is, to cases which would not have applied for admission to hospital wards under ordinary circumstances.

It cannot be said that any case has been cured by the treatment, but it must be stated that improvement has taken place in some of the cases of surgical tuberculosis. New eruptions of lupus nodules have made their appearance in Professor Kaposi's improved cases. There is also a difficulty in the improved cases as very large doses (5 centigrams and more) do not produce any reaction, and one does not know how far the dose of the injection can be raised. It is extremely difficult to say anything about the pulmonary cases. It seems that there are two different types. In one of them the temperature curve rises after every injection corresponding to the reaction, but returns to the previous level; while in the other the temperature curve does not return to its former level, and the patients remain feverish after the reaction has passed. The latter type is the less favorable for the treatment, and to it belong most of the fatal cases.

Not less difficult is the explanation of the anatomical facts, as the pathological changes occurring in the course of tuberculous disease have not been fully recognized till now, and there is no other disease which has been more neglected by pathologists on the Continent on account of its frequency. But in slight cases of laryngeal tuberculosis, where the changes could be observed clinically by the laryngoscope day by day, it could be stated that the injections of "Kochin" caused the rapid and extensive appearance of new ulcerations, sometimes of highly destructive tendency, and at the last meeting of the Medicinisches Doctorencollegium a case was shown where the ulcerative process occurring after the injections was an extensive one, which has never been observed by any of the Viennese professors. These observations seem to corroborate Virchow's statement that a dissemination of the tuberculous virus takes place in the body due to the injection. Referring to the diagnostic value of the fluid, it has been reported already to *The Lancet* that it produced local and general reaction in cases of leprosy, actinomycosis and fever (with small doses, one to two milligrams) in apparently healthy persons. The explanation of the action of his liquid given by Koch in his recent publication was also not believed to be satisfactory in medical circles here. It seems to me that the specific action of the liquid must correspond to a specific chemical substance contained in the mesoblastic tissues under certain pathological conditions—*e. g.*, tuberculosis, lupus, lepra, actinomycosis—and Koch's discovery will certainly stimulate the hitherto neglected study of pathological chemistry. At present we know only a single chemical substance peculiar to tuberculosis—viz., cellulose, or at least a substance exhibiting all the

reactions peculiar to cellulose, which was discovered some years ago in the blood and in the tissues of tuberculous cases by Dr. Freund, of Vienna. This discovery, reported in *The Lancet* of 1887, confirmed later by Dr. Kabrhel, of Prague, and which is also highly interesting from the naturalist's standpoint, did not receive much attention.

Treatment of Painful Menstruation.

Dr. E. H. Champneys, at the conclusion of several lectures on painful menstruation, writes as follows of the treatment of this condition in the *Lancet*, Dec. 27, 1890: It will be impossible to do more than indicate principles of treatment. These comprise treatment between and during the periods. In the first place comes the question of general mode of life. Generally speaking, this should not be too sedentary. Plenty of healthy exercise, and especially riding, will promote the circulation through the pelvis, and give the generative organs a better chance of developing. In the same connection must be mentioned the maintenance of the regular action of the bowels by laxatives, and particularly salines. This has the same purpose: to avoid stagnation of blood in the pelvis. It is probable that of all drugs in the treatment of chronic pelvic disorders, Epsom salts are the most valuable. Indeed, with constipation, none of this class improve, even if treated by the newest alkaloids. The diet should be simple and wholesome; in fact the patient should go into a sort of gentle training. During the pain most patients are better at rest, or even in bed; but some find their pain relieved by exercise, even unusually active. Pessaries (except the Hodge's pessary in a few cases of descent with retroflection, and except the stem pessaries) he believes to be absolutely useless. The stem pessaries are not always useless, but are dangerous, and should not be used. Incision of the os externum is useless; incision of the os internum is not always useless, but is highly dangerous. Among drugs, guaiacum, with or without sulphur, is sometimes useful, taken regularly in milk as a powder, or as a confection. Castoreum sometimes abolishes the spasm completely.

Dr. Champneys has known cases treated by nearly, if not quite, all the usual drugs unsuccessfully, get well suddenly as soon as castoreum was given. It is best given in the form of tincture, from twenty to thirty drops three or four times daily during the pain, with or without a few drops of tincture of nux vomica. A hot foot bath, and a good glass of hot gin-and-water at bedtime, at the beginning of the pain, is an old and valuable remedy. It probably acts by relaxing the vaso-motor and muscular spasm. The gin should be given once a month only. Ergot is sometimes useful by causing tonic contraction, and stopping what Reil would call the irregular, fibrillar, streaky, non-peristalic uterine contractions. Dilatation is the last resort. It is generally contra-indicated in the presence of inflammatory signs in the pelvis, even if old. It must be carried out with all antiseptic precautions, and is not, in his opinion, so trivial a proceeding as to be safely done in the consulting-room. The pain also is often agonizing, and is far greater than that caused by some operations for which anæsthetics are habitually given. For these reasons he prefers to perform dilatation at one sitting under anæsthesia, and with full antiseptic precautions, after ascertaining that the genuine dysmenorrhœal pain is evoked by dilatations of the os internum, a point which greatly improves the prognosis. Nothing can be promised, for dilatation may give temporary relief, permanent relief, or no relief at all. Still, considering the slight risk, he uses it rather freely, for there are cases which seem most unpromising, and yet are cured by it. He speaks of one such case; "a patient who had suffered for years, had had many treatments, including division of the cervix, which was followed by perimetritis, completely matting the posterior part of the pelvis. The pain was not only menstrual, but almost continuous. Her medical man in the west of England sent her to me to see what I could do for her. In spite of the very unfavorable conditions I dilated her cervix, and she lost from that time both menstrual and inter-menstrual pain. Her medical man wrote to me some time later to suggest that as she was so much better he might dilate the cervix again. I advised him to let well alone, and he took my advice."

The best time to dilate the cervix is about midway between the periods. Hegar's dilators do very well, or we can use the metallic bougies. The dilatation should not be pressed when great resistance is felt, or the cervix may be lacerated, even with fatal result. The object is not to enlarge, but to stretch the canal. But this stretching is gen-

erally not satisfactory unless the largest bogie varies from the size of a cedar pencil to that of the tip of the little finger. Two or three-bladed dilators are bad instruments; they stretch the canal unequally, and are liable to tear it. They are out of fashion in England, though not apparently in America and on the Continent.

Mammary Abscess in the Virgin.

Dr. Jule E. Marcus, of Cincinnati, gives in the *Cincinnati Lancet-Clinic*, January 17, 1891, an interesting account of a case of abscess of the breast in a young girl.

Cases of mastitis in the young, he says, are not altogether uncommon, as histories of cases are related, though in limited numbers, by various English, German and French authorities, in connection with the general subject of breast diseases of an inflammatory character. It is, however, a rare event for the mamma during the period of its development to go on to suppuration, though frequently subject to temporary sensations of pain, irritability and tenderness from various causes. Dr. Marcus has had, in a fairly extended practice, but this one case. The patient was seventeen years of age, a well matured, hearty appearing girl, who prided herself on never being sick. Her menstrual period arrived with her fourteenth year, and was always correct as to time and quantity. Her only illness previous to this abscess was an œdema of the left knee, in connection with fleeting pains in the ankle and shoulder of the same side, occurring during the last spring. She was placed on the usual anti-rheumatic remedies, with the result that in ten days she was quite well, and able to take her place at her desk as stenographer.

In June she had a painful condition of the chest on the left side, locating the trouble over the sternum, and beneath the breast and under the arm. It had only been within the past two or three weeks that she has become fully conscious to the fact that there was an irregular painful condition, constantly becoming more persistent, and claiming her attention.

The only symptom was pain of lancinating character, shooting from behind the breast, back to the muscles of the shoulder-blade, and extending downward in the side. There was no fever, no malaise; the girl had no cough, nor difficulty of breathing, and Dr. Marcus presumed there was another exhibition of her rheumatic trouble, and prescribed accordingly. She took salicylate of soda, hydriodic acid, etc., etc., but no marked improvement followed. Dr. Marcus examined the breast carefully, with no suspicion, however, of an inflammatory trouble being present, but could find nothing to explain the persistent pain, that was not varying in character, and was her only complaint. The girl began losing rest at night, but had no acute or excessive attacks of pain; never complained of throbbing or beating that would have led him to think an abscess was forming. Dr. Marcus again made a careful examination, but found no local visible signs, certainly no lymphatic enlargement in the region, and was therefore surprised when in the space of twenty-four hours a rapidly developed inflammatory action set in. Diffused redness, swelling, tenderness over the entire breast and neighboring muscles were present.

Dr. Marcus anticipated ' deep-seated trouble, and aspirated, drawing some matter and settling the diagnosis of a deep-seated, intra-glandular abscess of the mamma, chronic in character, and of long, slow development. On opening the lobes with a curved bistoury, cutting from the areola downward, with a deep, free incision, two teacupfuls of pus escaped. At the end of two weeks there remained a fistulous track.

Some weeks following, the breast again swelled, became tense and red, and intensely painful. In consultation with Dr. Ransohoff, the patient was anæsthetized, and the breast well opened. All the lower lobes were honeycombed with abscesses, with deep sacs over the pectoralis-major muscle. The gland was thoroughly scraped, and the abscesses broken up, drainage-tubes inserted, and iodoform gauze dressing applied, and the case did nicely, with such local and constitutional attention as is usually given to surgical cases.

Nothing remained at the end of the third week but some disfigurement of the gland.

Chronic abscess of the breast of the young is probably more influenced by catemenial disturbance than any other source. The gland at the period of puberty is in sympathy with the menses in a greater state of functional activity than at any time excepting the early period of lactation. Any unusual interference with the structural changes of the breast at this period would be apt to produce inflammatory action—not

frequently going on to suppuration, however. At the period of full development of the breast after the menstruation has been fully established, these gland inflammations are said to be of most common occurrence, and the slow developing chronic abscesses of more frequent occurrence than the acute. Cases of abscesses in both mammæ in a virgin are cited, establishing a pathological cause; where a traumatic origin would most likely suggest itself if only the one breast were involved.

In a brief review of the literature on the subject, Dr. Marcus found reference made by various authorities to cases of mastitis occurring in young subjects of both sexes. Velpeau relates histories of three cases not especially interesting. Bressler ralates a most interesting case of pyemia and death from breast abscess in a young female child. Following the abscesses in both glands, others developed in different parts of the body, and the child died of pyemic poisoning. Thomas Bryant relates histories of three cases of mastitis in virgins; all interesting, and in two cases recurrent abscesses developed after the lapse of considerable interval of time. In none of the recorded cases coming under my notice was a traumatic origin assigned, excepting Bressler's. In that case, squeezing the breast to produce a flow of milk was the accepted cause for the original inflammatory action in the breast; and he makes a point of calling attention to the fact that such a practice of working the breasts in young infants is common in the lying-in room, and may at any time be productive of harmful effects in the infant. Such a practice can only be deplored, and quite forcibly shows how necessarily attentive must be the practitioner to even the smallest details regarding the welfare of his patient in the sick-room.

Billroth says, in his treatise on the *Diseases of the Female Breasts:* "Inflammation, with formation of abscess after puberty, and unconnected with pregnancy, are very rare. The course is more tedious than in puerperal mastitis. Of the seven cases that have come under my notice, five suppurated, and two underwent resolution."

Artesian Wells in Iowa.

The *Engineering Record*, January 31, says that the director of the Iowa Crop and Weather Service, seems, from a recent article in the Iowa *State Register*, to have undertaken quite an important work in the direction of developing the subterranean water supplies of the State. It is probable that water can be obtained from artesian wells in nearly all parts of the State. But, as sinking such wells is an expensive operation, and, if done hap-hazard, may be barren of results, it is proposed to have made, with the assistance of a geologist, Prof. R. Ellsworth Call, a systematic geological examination of the whole State, so as to determine the localities in which desirable water-bearing strata would be found at moderate depths, making wells sunk therein reasonably sure of being successful. Director Sage hopes, in time, to be able to map in this way all such areas of artesian probability, for the benefit of farmers and others interested in obtaining water supplies.

To assist in this work circulars have also been sent out for the purpose of obtaining existing information relative to artesian wells already sunk, such as character of strata penetrated and especially of that in which the water was found, dip of strata, temperature and quality of water, amount of flow, etc., and also a record of unsuccessful wells.

This project, if pursued intelligently and thoroughly, must give results of great value to the citizens of the State.

Cancer of Bartholinian Gland.

At a recent meeting of the St. Petersburg Obstetrical and Gynecological Society, Dr. I. A. Woff has related an exceedingly rare instance of a solid new growth developing in a Bartholinian gland. A married woman, aged 42, who had been regularly menstruating since her fifteenth year, and had a labor at full term and two abortions, received a contusion of her left labium majus. Shortly afterwards she noticed at the spot a lump of the size of a pea, which began to gradually increase. On admission to Prof. K. F. Slavïansky's clinic, the patient had a tumor of the size of a goose's egg, involving the posterior part of the labium majus and an adjacent portion of the labium minus. On the inner surface of the former there was present an orifice, from which a dirty-looking fluid was oozing out. The new growth was excised together with portions of the labia. A microscopical examination revealed that the tumor was an adenoid cancer (*adeno-carcinoma*) of the Bartholinian gland.

During a discussion following Dr. Woff's

communication, Dr. Voskresensky said that he had also seen a case of a solid new growth of the gland. In 1887 a woman of 62 years had consulted him on account of indolent movable dense tumor. The latter had been excised fairly easily and proved to be of a fibroid structure. Two years later the patient returned with another tumor, which had developed in the same situation, but this time appeared to be of a malignant nature. On this occasion the excision was very difficult, being accompanied with an "enormous hemorrhage." Prof. A. I. Krassowski, the illustrious obstetrician and gynecologist, emphasized that solid new growth of the Bartholinian glands were extremely rare, while cysts and abscesses were fairly common. Personally, he had not come across a single case of the former kind. The speaker added that in his hands excision of Bartholinian cysts was invariably accompanied by a severe hemorrhage.—*Vratch*, No. 49, 1890, p. 1127.

Treatment of Paroxysmal Nerve Disorders.

In the *Practitioner*, January, 1891, Dr. Frederick Pearse has a short article on the treatment of paroxysmal nerve disorders, including in this class asthma, migraine and epilepsy. Dr. Pearse has great confidence in the efficacy of belladonna juice and chloral. In asthma he gives fifteen to twenty minims of the juice, with ten grains of chloral, every four hours, during an attack. To break up the habit, he gives the chloral and belladonna night and morning, or every night. He seeks to prevent attacks of migraine in much the same way, sometimes giving the chloral and belladonna every night for a few days before an expected paroxysm. Antipyrin, in large doses, he says is the most serviceable for the paroxysms of pain in migraine. Most persons, however, find small doses effective.

In the treatment of epilepsy, he has found chloral and belladonna useful to assist the bromides, and he mentions borax in thirty-grain doses with apparent approval.

Case of Ancephalia.

Dr. O. V. Lëonova, a medical woman of Moscow, communicates a remarkable case of an ancephalous monster, which was born alive (at full term) and survived for about *seventeen hours* (so that the parents had had enough time to baptize it). On the *post-mortem* examination (under Prof. D. N. Zernoff's guidance), the brain proved to be entirely absent, while the spinal cord terminated in the shape of a knot, which was adherent to a layer of cicatricial tissue, stretched horizontally across the base of the skull and representing the cranial vault. The said knot was found to constitute a rudimentary lower end of the medulla oblongata, consisting almost totally of white matter. The bulbar gray substance was represented by a single nucleus—namely, by that of the *nervus hypo-glossus*. In other words, the infant had been able to live for nearly a score of hours in spite of a complete absence of the respiratory centre.—*Transactions of the Moscow University Physico-Medical Society*, Nos. 3 and 4, 1890, p. 89.

Poison Glands of Toads and Salamanders.

Science, January 23, 1891, says that a microscopical study by Herr Schultz, of the skin of toads and salamanders, has yielded some interesting results. As stated in *Nature*, there are two kinds of glands,—mucous and poison glands. The former are numerous over the whole body; while the latter are on the back of body and limbs, and there are groups in the ear-region behind the eye, and in the salamander at the angle of the jaw. The mucous glands are spherical, have a clear, glassy appearance, and contain mucous cells and mucus: the poison glands, which are in regular strips on the salamander, are oval, much larger, and have a dark, granular look, from strongly refractive drops of poison, a good re-agent for which is copper-hematoxylin. The poisonous elements are from epithelial cells lining the glands. The mucous glands are for moistening the skin; and the liquid has no special smell, nor a bitter or acid taste. The poison glands are, of course, protective; and the corrosive juice is discharged differently in toads and salamanders, on stimulating electrically. In the latter it is spirted out in a fine jet, sometimes more than a foot in length; whereas in the toad, after longer action of the current, it exudes sparingly in drops. The physiological action of the poison has lately been studied by some Frenchmen. There is no reason, according to Herr Schultz, for supposing that the mucous glands sometimes become poisonous.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

NEUROSES OF THE GENITO-URINARY APPARATUS.

At a recent meeting of the Chicago Academy of Medicine, Dr. G. Frank Lydston made an address in regard to genito-urinary neuroses, in which he very properly limited the term to cases of purely functional derangement of the genito-urinary organs dependent upon pathological conditions of neighboring organs and conditions—probably of a spasmodic character—immediately dependent upon organic lesions of some portion of the genito-urinary tract itself. There are few morbid conditions of a functional character, which are so trying to the patient or so embarrassing to the surgeon, and in the experience of physicians it is found that they are apt to be more often consulted regarding these functional nervous derangements than for the actual diseases upon which they depend. In view of the vast amount of labor and talent that has been devoted to the study of the reflex neuroses of women incidental to pathological conditions of the uterus and its adnexa, it is, as Dr. Lydston said, surprising that more attention has not been given to analogous conditions in the male, due to disturbances of the generative organs, and especially of the urethra.

Taking as the point of departure the prostate, there will be found a close similarity between some of the morbid states affecting it and certain pathological conditions of the uterus. Anatomically and physiologically the prostate strongly resembles the uterus. The tendency of its muscular tissue to undergo degeneration, and to form fibro-myomatous growths is strikingly like that observed in the case of the uterus. It will be found that certain remedies which have a marked action upon the unstriated muscular fiber of the uterus have a somewhat similar action upon the prostate, this being especially true of the ergots of rye and corn and hamamelis. Certain sedative remedies have a special controlling effect upon irritative affections of the uterus, ovaries and prostate alike. Carrying the argument a little further, it will be found that certain irritations of the prostate produce effects very like that induced by utero-ovarian irritation in women. False spermatorrhœa — spermatophobia — pseudo-impotency, involving disgust for the sexual act, melancholia, hypochondria, neuralgias whether of contiguous or remote nervous filaments and nervous inhibition, amounting almost to complete paralysis, are all possible results of urethral or prostatic irritation, and these conditions are all represented by very similar disturbances, such as hysteria and its congeners in the female, due to morbid conditions of the generative organs.

One of the interesting features of stricture of the urethra is the ensemble of symptoms of a nervous character that is so often seen, these neuroses being often entirely disproportionate to the degree of organic trouble

present. Cephalagia, neuralgia in various localities, particularly sciatica, lumbar and intercostal neuralgia, are quite common, but are probably regarded by both physician and patient as coincidences rather than as bearing any consequential relation to the stricture. Associated with these symptoms are others, quite as prominent in some cases, of a purely mental character, such as melancholia, disturbed sleep, hypochondria, incapacity for intellectual effort and deterioration of business capacity, perhaps associated with great irritability of temper. Disturbed digestion and general impairment of nutrition are quite constant. That these various abnormal conditions depend upon the stricture, Dr. Lydston said, is never appreciated fully until that organic disease is cured, when the complete restoration to health demonstrates their true relation to the primary source of irritation. Some cases of gleet are associated with considerable mental depression, which is commonly ascribed to the moral effect and the supposed drain upon the system. This lack of mental equilibrium may arise from reflex irritation through the sympathetic system, which is so closely allied with the functions and nutrition of the sexual organs. Morbid conditions of the urethra not only cause reflex neuroses in other portions of the body, but they are frequently the reflex result of disease of contiguous strictures. Thus Dr. Lydston has noted cases of spasmodic stricture depend upon hernia and varicocele, and Dr. Otis has described some very interesting cases of chronic spasmodic stricture of reflex origin. Operations about the anus are frequently followed by spasmodic stricture and consequent urinary retention and morbid conditions of the interior portion of the urethra often cause reflex disturbances of the deeper portion of the canal or indeed of the bladder. This is very familiar in connection with the results of contraction of the meatus.

These remarks of Dr. Lydston, who has made a special study of the subject of which he speaks, may well attract attention. In one sense it can hardly be said that the remote effects of disturbances of the genito-urinary apparatus have been neglected, for many quacks have dwelt upon them too much to their own advantage. But it is true that the nervous derangements due to disturbances or disease of the genito-urinary apparatus of men have not been studied as thoroughly and as systematically as their congeners in women have been, and it may be well to have this point impressed upon physicians, so that some of the zeal now perhaps needlessly spent upon the genitalia of women may be directed to recognizing and curing the ailments of the sterner sex.

TRANSPERITONEAL HYSTERORRHAPHY.

From time to time the various methods for permanently anteverting the retro-displaced uterus have been commented upon in the REPORTER. Dr. Florian Krug, of New York, has proposed a new method of ventro-fixation of the uterus without opening the peritoneal cavity. His method is applicable only to cases of obstinate, movable, backward displacements of the uterus, which have not proven amenable to other treatment. The technique is as follows: The patient is put in Trendelenburg's position, the usual preparations for an abdominal section having been made. An assistant now seizes the anterior lip of the cervix with a tenaculum, and inserts a sound into the uterus, and a catheter into the bladder; and brings the uterus forward, by gentle efforts, against the abdominal wall. A small incision is now made through the linea alba down to the peritoneum, at the point which is selected for the attachment of the uterus. The finger inserted into the wound can locate the fundus, and also the bladder, when the sound and the catheter are alternately pushed upon. A special needle is now passed through the abdominal wall into the peritoneal cavity, and is made to de-

nude about one square inch on the anterior surface of the uterus, the needle then being passed through the body of the uterus and made to emerge at a place opposite to the point of entrance. It is now threaded with silkworm gut and withdrawn. The suture is now tied, and usually suffices to close the wound. From five to eight minutes are required for the operation. Dr. Krug has operated upon six patients with good results.

The test of the value of any operative procedure is the results to be obtained by its use. At the same time, the writer does not believe that the procedure proposed by Dr. Krug has a wide field of usefulness. Many retro-displacements of the uterus, in which the uterus is freely movable, give rise to no symptoms, and require no treatment. Most cases which cause suffering are curable by the proper use of tampons and a pessary, and it is only the small remainder for which the operation is recommended. In these cases the operation comes in competition with Alexander's operation, with hysterorrhaphy done without incising the abdominal wall (Kelly), and with hysterorrhaphy preceded by abdominal section (Olshausen, Kelly). It is difficult to see how that this method gives a better fixation than is obtained by ventro-fixation without incision of the abdominal wall, and the writer is aware of no case in which permanent fixation has been secured by this method. The subsequent behavior of these six cases will be awaited with interest, for if the fixation prove permanent, Dr. Krug will prove a benefactor, as providing an easy method of curing certain obstinate, backward displacements of the uterus.

NASHVILLE JOURNAL OF MEDICINE.

The *Nashville Journal of Medicine and Surgery* opens the new year with a new and very much improved form, and we hope will enter a new era of success.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

ESSENTIALS OF PRACTICE OF MEDICINE. Arranged in the form of questions and answers. Prepared especially for students of medicine. By HENRY MORRIS, M. D., Late Demonstrator, Jefferson Medical College, etc. With a very complete Appendix on the Examination of Urine. By LAWRENCE WOLFF, M. D., Demonstrator of Chemistry, Jefferson Medical College. Small 8vo, pp. xv, 426. Philadelphia: W. B. Saunders, 1890. Price, $1.00.

This volume includes *The Essentials of Practice*, by Dr. Morris, and *The Essentials of the Examination of Urine*, by Dr. Wolff, which have heretofore appeared as separate parts, forming Nos. 8 and 9 of Saunders' series of compends. The plan of these books is too well known to warrant discussion, and the necessarily brief manner in which diseases are handled almost disarms criticism. In looking over the book, however, several improvements have been suggested. For example, in speaking of ordinary facial erysipelas, Dr. Morris would have done well to make it clear that sore throat and swelling of the cervical and sub-maxillary glands generally precede an attack, and that a relapse is liable to occur as long as the throat and nasal passages remain in an unhealthy condition. Under typhlitis and peri-typhlitis, also, the author should have stated that these affections are really, in the great majority of cases at least, attacks of appendicitis. Again, he is in error when he says that the urine of *chronic* parenchymatous nephritis is "scanty, high-colored and of high specific gravity." It may be diminished in quantity, but it is not scanty or high-colored, and the specific gravity is lower, instead of higher, than normal. The author makes substantially the same statement regarding the urine of *acute* parenchymatous nephritis, of which disease, of course, it is true.

Dr. Wolff's portion of the book has been reviewed recently in the REPORTER, so that no special mention need be made of it now.

In spite of the defects which we have noted, the book is a good one, and it will prove very helpful to students preparing for examination.

A TEXT-BOOK OF MATERIA MEDICA, PHARMACOLOGY AND SPECIAL THERAPEUTICS, with many new remedies of late introduction. By I. J. M. Goss, A. M., M. D., Professor of the Practice of Medicine in the College of Eclectic Medicine and Surgery, Atlanta, Ga., etc. Second edition. Revised by the author. 8vo, pp. xlviii, 586. Chicago: W. T. Keener, 1889. Price, $5.00.

This is a book on materia medica and therapeutics written by an eclectic for eclectics, as its rather long title indicates. Theoretically, electicism, that is to say, the method of one who picks and chooses what he believes to be best, without following any leader or theory, is the method adopted by every intelligent practitioner of medicine; practically, however, those who adopt the title eclectic have a theory as to the action of medicines, and, as might be expected, it is as false as that which forms the basis of homœopathy or allopathy. The theory of eclecticism, as stated by Dr. Goss, is: "That when medicines are introduced into the system they are digested, and being absorbed and circulated through the system, they have, *per se*, an affinity for certain parts of the organization (*sic*) upon which they have a specific action, and are then elim-

inated." It would appear from this definition that the real eclectic is the remedy, which selects the part upon which to act, and not the prescriber, who chooses the remedy.

The usual assertions are made about medical science advancing fast, and that "ere long '*pathys*' and '*isms*' will no longer clog the wheels of advancement." We could wish that knowledge had traveled so far that even Dr. Goss would know that no intelligent man believes in the theory which the term "allopathy" expresses, and that no school teaches it.

As to the arrangement of the book, nothing need be said, except that it is unscientific. It is, nevertheless, of considerable value as a work on therapeutics, for most, if not all, of the standard remedies are considered fairly, with many new ones. Of the value of the latter one cannot judge from Dr. Goss's statements alone, because he is too prone to speak dogmatically. They may, however, be very valuable, and Dr. Goss has done a real service in calling attention to them. The chief fault of the book is the fact that the impression left upon the reader is that diseases are groups of symptoms instead of processes, having definite causes, courses and results. One who followed Dr. Goss's teachings might become an excellent dispenser of drugs, and might give great relief to his patients; but he never could become a physician. One cannot help suspecting, also, that Dr. Goss praises many of his remedies unduly, and that the effects which are asserted to follow their use will by no means surely follow when the remedies are used by others. Of this charge, however, Ringer and others who ought to know better are equally guilty.

CORRESPONDENCE.

Antipyrin in Puerperal Fever.

To the Editor.

Sir: I was somewhat surprised to read in the Reporter for June 31, the following, in an article quoted from the *Lancet*. "Dr. McBeath has never noticed in any publication that antipyrine has been used with success in puerperal fever." Not to go any further, I may say that as long ago as 1887, I used antipyrin in a bad case of "puerperal fever" in twenty-grain doses—smaller quantities having proved ineffectual—with benefit, so far as reducing a high temperature (105°+,) and quieting delirium and restlessness were concerned. That case and others were reported in the Reporter during that year, I think. I have learned to esteem antipyrin highly in all diseases characterized by restlessness, delirium and high temperature, and have not observed any bad effects, perhaps for the reason that I invariably accompany or follow it with either an alcoholic or aromatic spirits of ammonia. Nevertheless, I do not believe it exerts any specific action in puerperal fever. From what I have seen of this disease, I believe that the treatment having most to commend it is that based on what is assumed when it is spoken of as puerperal septicemia, and that the good effects obtained by antipyrin may likewise be obtained by phenacetin or antifebrin.

Yours truly,
Stanley M. Ward, M. D.
Scranton, Pa.

Medical Examiners' Bill in Pennsylvania.

To the Editor.

Sir: Canada and eighteen of own States have passed laws establishing "examining boards" as proposed by the "Riter" bill, now before the Legislature of Pennsylvania, and in consequence the States not so protected are receiving more than their quota of piebald doctors.

The public in this State are protected by Inspectors of Weights and Measures from dishonest tradesmen, and druggists are compelled to qualify before a State Board of Examiners, and why should they not be protected from incompetent physicians? As the law now stands, no evidence of medical knowledge is required before engaging in the practice of medicine. The most ignorant has only to make an affidavit that he has been in practice for ten years to become a registered physician, even though he has to make his mark, because he cannot write his name.

The medical college with hospital attachment has become, of late, one of the money-making industries of the country, with unlimited capacity, free raw material, and the motive power supplied and the running expenses shared by the public by means of the "*charity act*," by appeals for aid for the hospital.

By the terms of the "Riter" bill, all desiring to practice medicine must pass a satisfactory examination before duly-appointed medical examiners for the State, irrespective of schools or systems. The eclectic is left free to make his own selections; the electropath can still perform miracles with a fifteen-dollar battery; the hydropath can drown every known disease in water; the faith curer and magnetic healer can pray and magnetize to his heart's content; the homœopath can still administer his preparations of the matter from small-pox sores, or the itch pustules of the negro, his solutions or powders of bed-bugs or cock-roaches, of

the acarus found under the wing of the Philadelphia house-fly, of tarantulas, snakes, red ants, spiders, potato-bugs, plant-lice, snails, wood-lice, skunks, wasps, lizards, toads, vipers, or guano, or of the excreta of the whale, etc.—all of which will be found in the list of materia medica contained in the *American Homœopathic Pharmacopœia*, Boericke & Tafel, 1883.

All former legislation on this subject has been effectually frustrated by the above schools, especially the homœopaths, who have been most bitter against any law which would compel them to undergo an open and public examination of their fitness to practice medicine. Yet, notwithstanding the above fact, by posing as martyrs they succeeded in obtaining State aid to the amount of fifty thousand dollars last year, and are aiming to get at double the amount this year.

Many cases might be cited to demonstrate the necessity for the passage of the proposed bill, but the following will suffice:

An innocent, hard-working German, suffering from stone in the bladder, applied for treatment to a member of the Philadelphia County Medical Society. He had been under treatment for over a year, of a woman who sold bread from her shop in the morning and practiced medicine when not otherwise engaged. According to his statement, she gave him "yarb" teas to drink, pulled and manipulated his testicles, causing him intense pain; instructed him to urinate in pigs' bladders and to suspend them on a tree, and as these bladders rotted he would be relieved of his trouble, but should he ever again look at that tree his trouble would return. This not being successful, she instructed him to urinate on a broom, which would generate a current of electricity which would pass from the broom, through the stream, to his bladder, and thereby effect a cure. This woman was prosecuted by the Philadelphia County Medical Society, with a number of others, for practicing without being registered. She pleaded guilty in order to suppress the foregoing facts, which would have appeared at the trial, paid the fine imposed by the Court, then registered under the ten years' clause of the Registry Act, and, if still living, is one of Philadelphia's registered practicing physicians, with all the privileges of the most learned and skilful practitioners of the day.

If the homœopaths want the community to have such persons practicing, let them continue to oppose the Medical Examiners' Bill—if they do not, let them support it, as the only measure proposed which would give the community a satisfactory method of compelling all who assume such responsibilities to attain a definite standard of education, and the only one which could not be evaded by medical colleges.

Yours truly,

J. H. Lopez, M. D.

Philadelphia.

Notes and Comments.

Information about the Army Medical Department.

The Medical Department of the Army consists of one Surgeon-General with the rank of Brigadier-General; one Assistant Surgeon-General, one Chief Medical Purveyor and four Surgeons with the rank of Colonel; two Assistant Medical Purveyors and eight Surgeons with the rank of Lieutenant-Colonel; fifty Surgeons with the rank of Major; and one hundred and twenty-five Assistant Surgeons with the rank of First Lieutenant of Cavalry for the first five years of service, and of Captain of Cavalry subsequently until their promotion by seniority to a majority.

With the rank stated in each case the pay and emoluments of the rank are associated. The salary of each grade is a fixed annual sum, payable monthly; but at the end of each period of five years of service the annual sum representing the pay of the grade is increased by ten per cent. until forty per cent. is added. After twenty years of service the forty per cent. additional continues to be drawn, but the further increase of the pay by ten per cent. additions ceases, *i. e.*, an officer, although he may have served twenty-five or thirty or more years can, under existing laws, have no more than forty per cent. added to his pay proper by way of increase for length of service. The pay of a first lieutenant of cavalry, or of a medical officer during the first five years of his service is $1,600 per year, or $133.33 per month. At the expiration of his five years of service he becomes, by virtue of that fact, a captain, and his pay is that of a captain of cavalry, $2,000 per year, increased by ten per cent. for his years of service, viz., $2,200 annually, or $183.33 monthly. At the end of his tenth year of service this rate of pay is increased by the service-addition to

$2,400 annually, or $200 per month, and after five years more the service-addition makes his pay $2,600 annually, or $216.67 per month. If he continue in the rank of captain, at the end of twenty years of service his monthly pay becomes $233.33; but about this time promotion to a majority is usually obtained, and a major's annual pay of $2,500 with forty per cent. added, makes the monthly pay of the major and surgeon $291.67. Subsequent promotion, investing the individual with the rank of lieutenant-colonel, colonel and brigadier-general, augments the monthly pay respectively to $333.33, $375.00 and $458.33. Cumpulsory retirement at the age of sixty-four years increases the rapidity of promotion to the younger men; and when retirement is effected either by age, or by the accidents of service prior to reaching the retiring age, the rate of pay subsequently drawn is seventy-five per cent. of the total salary and increases of the rank held by the individual at the time of his retirement. Thus, a major retired for broken health after twenty years' service draws seventy-five per cent. of $291.67 per month; a colonel retired for age, seventy-five per cent. of $375.00. The medical officer has the right of selecting quarters in accordance with his rank, and when stationed in a city where there are no Government quarters, commutation money, intended to cover the expense of house rent, is paid to him. The Government provides forage and stable room for the horses of the medical officer, and when traveling under orders the expenses of transportation are paid by the Quartermaster's Department.

Among the privileges granted to medical, as to other officers of the Army, is that of leave of absence on full pay. The authorized leave amounts to thirty days annually. This leave is not forfeited if not taken during the year, but is credited to the officer, who may thus accumulate a continuous leave of four months on full pay. If he desires to be absent for a longer period than four months, and the permission is accorded him, he is reduced to half-pay for all time in excess of the four months or maximum of cumulated leaves of absence. Absence from duty on account of sickness does not affect the relations of the officer with the paymaster; he continues to draw full pay.

A commission in the Medical Department of the Army is an instrument which is good for life, premising conduct consistent with its retention on the part of its possessor; but it involves no contract which binds the individual to service for any given number of years. On the contrary, should the medical officer find on experience that civil life has greater attractions for him than that of the Army, there is nothing to prevent him from at any time tendering the resignation of his commission.

A young medical officer on appointment is usually assigned to duty for a few months at some large post where there are other officers of his department, to afford him opportunity of becoming acquainted with the requirements of the Army Regulations and the routine duties of military life. After this he goes to some post west of the Mississippi river, where he serves a tour of duty of four years. An assignment in the east follows the leave of absence which is usually taken at this time; and in after years his stations are selected so as to give him a fair share of service at what may be called desirable posts as an offset to the time spent at less desirable stations.

Candidates for appointment to the Medical Corps should apply to the Secretary of War for an invitation to appear before the Army Medical Board of Examiners. The application should be in the handwriting of the applicant, should give the date and place of his birth and the place and State of which he is a permanent resident; it should be accompanied by certificates based on personal acquaintance from at least two persons of repute as to citizenship, character and moral habits. Candidates must be between twenty-one and twenty-eight years of age (without any exceptions), and graduates of a regular medical college, evidence of which, the diploma, must be submitted to the Board. The morals, habits, physical and mental qualifications and general aptitude for the service of each candidate will be subjects for careful investigation by the Board, and a favorable report will not be made in any case in which there is a reasonable doubt.

The following is the general plan of the examination:

I. The physical examination will be rigid; and each candidate will, in addition, be required to certify "that he labors under no mental or physical infirmity, nor disability of any kind, which can in any way interfere with the most efficient discharge of any duty which may be required."

II. Oral and written examinations on subjects of preliminary education, general liter-

ature, and general science. The Board will satisfy itself by examination that each candidate possesses a thorough knowledge of the branches taught in the common schools, especially of English grammar, arithmetic and the history and geography of the United States. Any candidate found deficient in these branches will not be examined further. The examination on general science will include chemistry and natural philosophy, and that on literature will embrace English literature, Latin, and history, ancient and modern. Candidates claiming proficiency in other branches of knowledge, such the higher mathematics, ancient and modern languages, etc., will be examined therein, and receive due credit for their special qualifications.

III. Oral and written examination on anatomy, physiology, surgery, practice of medicine, general pathology, obstetrics and diseases of women and children, medical jurisprudence and toxicology, materia medica, therapeutics, pharmacy and practical sanitation.

IV. Clinical examinations, medical and surgical, at a hospital, and the performance of surgical operations on the cadaver.

Due credit will be given for hospital training, and practical experience in surgery, practice of medicine and obstetrics.

The Board is authorized to deviate from this general plan whenever necessary, in such manner as it may deem best to secure the interests of the service.

The Board reports the merits of the candidates in the several branches of the examination, and their relative merit in the whole, according to which the approved candidates receive appointments to existing vacancies, or to vacancies which may occur within two years thereafter. *At the present time there are five vacancies to be filled.*

An applicant failing in one examination may be allowed a second after one year, but not a third.

No allowance is made for the expenses of persons undergoing examination, but those who are approved and receive appointments are entitled to transportation in obeying their first order assigning them to duty.

Politics and Pension Examiners.

In an editorial, the *Indiana Medical Journal*, February, 1891, speaks as follows in regard to a recent appointment by the President.

The *Journal* is not a partisan paper, but occasionally politics trends so closely upon the interests of the profession and the welfare of the sick, that our readers will excuse us for entering a solemn and vigorous protest against the appointment by President Harrison of an incompetent negro, S. A. Elbert, said to be a physician, upon the Examining Board for Pensions in this city, displacing Dr. R. F. Stone, the ablest physician on the Board and a veteran Union soldier. This appointment is, to say the least, an outrage upon common decency, and an insult to every soldier residing in Indiana and every reputable physician of Marion county and the State.

If Elbert were a physician of eminence or marked ability in any department of medicine, there might be some word said, by the administration, in extenuation of the act reflecting upon the ability of no less than five ex-Union soldiers, now reputable physicians, who were applicants for position upon the Board at the beginning of this administration. But such is not the case. This negro does not approach mediocrity in medical attainments, and it is doubtful if he could give the origin and insertion of one muscle in the human body.

The appointment is an inexcusable, indefensible and disgraceful blunder. From among two hundred physicians of this city and county, many of whom are men of marked ability in the profession, the little General is unable to select one who can do honor to the place, himself, the appointing power, and the G. A. R., so he is constrained to select one of the two sable followers of Æsculapius. The purpose of the appointment is apparent to the most obtuse; yet it remains to be seen whether this appointee can wield a political influence which will overbalance that of the two hundred physicians of Indianapolis, the five thousand physicians of Indiana, and the thousands of veteran soldiers who are held in contempt by this administration, and compelled to submit their claims for pensions to the judgment of an incompetent negro doctor.

The various Boards of Examiners for Pensions were created by the government for the purpose of fairly adjusting the claims of wounded and diseased soldiers, and it was intended that they should be composed of the very best medical talent available, in order that justice might be done to both soldiers and the government. But it has remained for Benj. Harrison to not only vio-

late his pledge made to the soldiers, during and after the campaign of 1888, viz., that that section of the revised statutes making it obligatory—other things being equal—to appoint soldiers to places of remuneration under the government in preference to civilians, should be enforced, but he has deliberately, with this promise still fresh upon his lips, prostituted the office of Pension Examiner to the basest political purposes, unmindful of his sacred obligations to the Union veterans and their interests, the claims of comradeship, and the sanctity of his oath of office.

We do not believe there lives a soldier in Indiana who is so lost to self-respect as to present himself before the Indianapolis Board, as now constituted, for examination; nor can the other members of the Board preserve their dignity, self-respect, and the respect of the profession in any other way than by resigning.

At the stated meeting of the Marion County Medical Society, January 20, there being forty members present, the following resolutions, presented by Dr. Frank Ferguson, were unanimously adopted:

Resolved, That the recent action of the President of the United States, in removing from the Board of Pension Examiners of Indianapolis an honored member of this Society and a veteran Union soldier, in order to give place to one who is not, and who never has affiliated with the profession, and who does not possess the necessary qualifications for the important trust thus committed to his hands, is a base and inexcusable prostitution of the office of Pension Examiner to partisan purposes and an insult to every reputable physician in this city and State.

Resolved, That the Secretary is instructed to forward a copy of these resolutions to the President of the United States and to the daily papers of this city.

[It would be pleasant to know that there was some better reason for the President's action in this matter than that which our contemporary's remarks indicate—or that the President had corrected his error.]

Statement by Tait Corrected.

Sir Spencer Wells writes to the *Lancet*, January 31, to correct an assertion made by Mr. Lawson Tait, and seems to do so pretty effectually. He says that at the meeting of the British Gynecological Society, December 12, 1888, Mr. Lawson Tait said "he had a specimen to show which bore very much upon what had just been said; he showed the appendages from a lady, thirty-nine years of age, with a very remarkable history. She had been married at the age of seventeen or eighteen, and had two children within twenty months of her marriage. Soon after her second confinement she contracted gonorrhœa from her husband, and she had never known what it was to be well since. She had led a life of single misery for several years. Then she married again, but her health did not improve, and she never became pregnant by her second husband, so that ever since nineteen or twenty she had been absolutely sterile. During the last seven years she had been the patient of a distinguished gynecological baronet, who had, however, failed to relieve her. Ultimately she had been referred to him and he had operated. She had double pyo-salpinx of old standing, and it was very difficult to say which was tube and which was ovary. There were abscesses in both ovaries, and if he had attempted to tap them from the vagina, he would have been obliged to tap several cavities. Instead of doing anything of the kind, he opened the abdomen a month since, and the patient was now practically cured. A case like that was worth a dozen hypothetical imaginations. There was a woman who had been an invalid for years, who could have been relieved at any time, who had been under the care of all the well-known specialists of London, many of whom had declared that there was nothing the matter."

In the letter published in the *Lancet*, January 24, Tait adds that if anybody is answerable for this failure "it is Sir Spencer Wells, who, during seven long years, treated this poor woman uselessly by pessaries, etc." And he adds that the case is "not a failure," . . . the patient is "absolutely cured, for I have the diseased parts in a bottle."

Sir Spencer Wells says: "This lady is now in London. I have submitted the following questions to her, and I add her replies:

"1. During the seven years 1881–88 were you under my care, and did I fail to relieve you? *Reply:* I consulted you in 1879, after Dr. Palfrey had failed to do me any good. You operated on me in the summer of 1879; I was in good health after that until you again operated on me in 1880.

After that I enjoyed good health until 1887.

"2. Had you, before 1888, been 'an invalid for years,' or 'led a life of single misery for several years?' *Reply:* Except between my second confinement and 1879, I had been in good health.

"3. After your second confinement had you 'been absolutely sterile?' *Reply:* I had two children after my second confinement—one born dead, one lived two weeks and I had one miscarriage at three months.

"4. Have you been 'under the care of all the well-known specialists in London, many of whom declared that there was nothing the matter?' *Reply:* You are the only medical man I consulted in London between 1879 and 1888, and no one ever told me that there was nothing the matter.

"5. Did I treat you 'for seven long years by pessaries, etc.?' *Reply:* No, you never used a pessary; nor, after your second operation in 1880, treated me except for slight ailments, and that seldom. In 1887, while you were abroad, I was treated by Mr. Smith, of Brighton, after a carriage accident and was recovering when you returned.

"6. Remembering your state before and after the operation performed at Birmingham in November, 1888, has that operation proved to be, in your opinion, a 'practical cure' or a 'deplorable and disastrous failure?' *Reply:* A decided failure.

"I need only add to this the fact that the operation I performed in 1879, assisted by Mr. Thornton, was amputation of part of the elongated cervix uteri. Dr. Palfrey had repeatedly injected solution of perchloride of mercury into the substance of the cervix, and it was feared that the disease was papilloma or epithelioma. Examination proved that it was simple hypertrophy of the utricular glands, or adenoma. About a year after this amputation, the remains of the cervix showed some tendency to enlarge and proliferate, and I destroyed the left side by the actual cautery. For two or three days after this there was a good deal of pain and some fever, but they soon subsided, and until 1887—about seven years—the patient was as well as most people, and for several months after her second marriage, in February, 1888, remained in good health, riding, rowing and walking four or five miles without fatigue. Since the operation in November, 1888, she has been a confirmed invalid. The failure to the husband has been 'disastrous' in expenditure; to two devoted daughters in health and anxiety from continuous nursing; to the patient 'deplorable' in more than two years' almost continuous suffering and shattered health. It is a very poor consolation to her to be assured that she is 'absolutely cured' because her 'diseased parts are in a bottle.'"

Medical Examiner's Bill in Pennsylvania.

Under the head of Correspondence, the *New York Medical Times*, February, 1891, publishes the following, which is especially interesting as appearing in a journal long sailing under the homœopathic flag.

Medical legislation in Pennsylvania is in an unsettled condition. At the last meeting of the Legislature the Medical Examiners' bill was defeated through the active efforts of the New School. In anticipation of renewed efforts for its passage this year, the New School will offer a substitution measure entitled "An act to establish a State Board of Medical Education." This board is to consist of nine members to be selected equally from three lists of ten names submitted by the State medical societies "to the intent that the three systems of medicine, homœopathic, allopathic and eclectic, be equally represented thereon."

The duty of the board is to regulate the extent and character of the preliminary education to be required of all medical students; to fix the minimum curriculum of studies in medical colleges, provided that the course shall be not less than four years, which shall include three years of lectures. Each graduate of colleges as upon evidence of the dean, has conformed to the requirements of the board, shall receive a certificate entitling him to register in any county of the State.

Graduates of other colleges whose standing is approved by the board receive a similar certificate allowing them to practice, but if from colleges of a lower standing they must first pass an examination which shall apply to their preliminary education as well as medical knowledge.

Should the board discover after the passage of the act, that any medical college has granted the degree to any one deficient either in preliminary or final examination it shall proceed against such college for infringement of the law. The penalty for the first offense is a fine, and for a second offense a fine and the certificate withheld from future graduates except upon examination before the board. In conviction for a

third offense the charter of said college shall be annulled.

It is difficult to see what advantage this bill has over a fair Medical Examiners' bill. Both admit the principle of outside interference with the right of college faculties to decide who shall enter upon the practice of medicine. The Medical Education bill does this by prescribing the curriculum and then approving the work of colleges living up to it. The Medical Examiners' bill does it by requiring a final examination of all graduates before they shall be allowed to practice in the State. The latter method is the simpler one, and makes no discrimination in favor of medical colleges located in the State, and is similar to the methods adopted by the profession in other States.

It would be difficult for the Board of Medical Education to decide that other medical colleges in the United States were living up to its standards, because even in Pennsylvania, to make sure of this fact, part of section 6 provides that "the board shall delegate one or more of their number, who from time to time shall make an inspection of the methods of instruction employed and the facilities for teaching, in each such medical college and annually report the same to the board."

The New School bill, by removing the fear of another examination from all who graduate at colleges in the State, legislates for the colleges rather than for the profession at large, because they would attract more students by holding out as an inducement the freedom of practice in Pennsylvania to all their graduates, and it is very probable that a large number of the latter would enter the already overcrowded ranks of the profession in that State.

Let Pennsylvania pass a Medical Examiners' bill that is fair to the whole profession of that State, and when the remaining States have done likewise, then let us have a National Board which shall prescribe a uniform examination for all graduates in medicine (this was first suggested by Prof. Osler of Johns Hopkins), so that having passed the examination in Pennsylvania, the certificate of that examining board shall be accepted by every other State as granting the right to practice medicine.

State Board of Health.

At the quarterly meeting of the State Board of Health of Tennessee, January 6, 1891, the Secretary, Dr. J. Berrien Lindsley, read a report, in which he said that of the forty-four States forming the American union, thirty-four have created Boards of Health. These differ widely in their powers and functions and also in the means at their disposal for efficient work. Some are merely advisory bodies. Others have great executive power. Some are so niggardly endowed as to have only a nominal existence. Others are so munificently supported as to be seen and felt through beneficent work in every section of their field.

The older States of the Northeast first recognized the value of such agencies for promoting the public welfare. Among these Massachusetts and New Jersey are prominent, appropriating thousands annually for their support, and in addition printing for distribution among the people large editions of reports and circulars.

In no part of America have the objects of such Boards met with so great favor as in the new, wide-awake and rapidly advancing States of the Northwest. The great farming States, especially Michigan, Illinois and Minnesota, may be mentioned as illustrations. The volumes issued by the State Boards of Michigan and Illinois have given those States a national—even more, a European reputation. Michigan and Minnesota are also distinguished for the wonderful cooperation received from local Boards, which in each State number fifteen hundred or more.

In every instance where a State Board has been furnished with liberal means it has found favor with the people and has become a permanent and valued portion of the State machinery, second alone to its kindred branch of Public Education.

Tennessee has a Board of Health rather peculiar in its structure, capable of furnishing to the State great results at a minimum of cost, as has been tested more than once in its brief history.

It is in fact a collegiate body, composed of five medical experts, each proficient in his own department, and of two men eminent in railroad and mercantile circles. Each of these members is at the beck and call of the State whenever his services are needed, and at very moderate cost. In addition, the Secretary, who is not a member of the Board, is always ready on a moment's notice to visit any locality upon its order.

The ordinary work of the Board and the readiness for extraordinary occasions is

greatly facilitated by the publication of a monthly bulletin [from which the REPORTER makes this abstract] which is systematically circulated throughout the State, and likewise sent to public libraries, boards of health, and similar institutions in all the States as well as to a very large list of exchanges. The bound volumes take the place of annual reports, for which there has been no statistical material. This *Bulletin* is also the journal of the State Weather Service, an indispensable agency of all live States, which was about to perish five years ago, when this Board, recognizing the intimate connection of climatology with the work, saved its life.

Five and a half years' experience fully demonstrates the wisdom of this action. Practically, it has been copied by what is virtually the National Bureau of Health at Washington.

A prominent feature in the *Bulletin* is the publication of truthful vital statistics, without favor or partiality. Of course, with the incomplete and perhaps exaggerated returns from 1885 to 1890, errors were unavoidable. All statisticians understand this. From now on these statistics should be accurate and reliable. One marked result of the steady circulation of this information has been greatly increased confidence of life insurance companies in Tennessee as a field for their business. A signal instance of this is the erection in Memphis of a noble structure by one of the most noted companies in the world.

Not less noteworthy is the effect of this *Bulletin* in directing the attention of desirable emigrants to our State. One of the greatest treasures Tennessee can boast is its beneficent climate. Nowhere else has this life-giving wealth been so well displayed as in the sixty-six numbers of this monthly, steadily sent to those throughout the Union who understand its language and can appreciate its meaning.

Resorcin in Diphtheria.

One of the few of the numerous drugs introduced in recent years which has stood the test of time is resorcin, which has been chiefly used for skin complaints, but has also been found useful in whooping-cough. The *Lancet*, December 20, 1890, says that Dr. Andeer, of Munich, gives, in the *St. Petersburger Med. Wochenschrift*, 1890, a summary of its advantages in the treatment of diphtheria. He refers chiefly to French authors. Leblond and Baudier have shown, in an exhaustive treatise, that in resorcin we have an antiseptic of the first rank; it exerts a destructive influeuce on micro-organisms, even in extremely dilute solutions, and in spite of the rapidity with which it is absorbed and again excreted from the body. Its easy solubility in all fluids, its rapid evaporation by heat, in addition to the completeness with which it mixes with the air, without any discomfort to the patient, render it suitable for the destruction of all pathogenic micro-organisms. Roux and Yersin have conclusively demonstrated that diphtheria only attacks open wounds, consequently all further injuries to the parts attacked ought to be carefully guarded against, so that all mechanical modes of removing the diphtheritic membranes are to be avoided, and the same may be said of the use of drugs for a like purpose. The latter are particularly dangerous on account of any excess which may fall on healthy tissues, so preparing fresh ground for the morbid process. Any antiseptics which may be used ought to have no injurious effects on the parts not attacked. Such an antiseptic is a 10 per cent. solution of resorcin in glycerine.

Several severe cases of diphtheria have been successfully treated in this way by Leblond, Baudier, Besnier, Thorens, and others. They advise that the solution should be applied by means of a brush every hour during the day and every two hours during the night; also that the air of the room should be kept saturated by means of a spray apparatus containing a watery 5 per cent. solution of resorcin.

The conclusions to which the authors named above have come are as follows: 1. When the larynx is not affected the disease usually disappears in from six to ten days. 2. If the treatment is adopted at the commencement of the attack, the formation of membrane is very slight, and the larynx generally escapes. 3. In advanced cases, if the glands are swollen, and plaques of membranes numerous over the back of the throat, after forty-eight hours' treatment by resorcin the swelling of the glands begins to subside, and the formation of any fresh membrane is prevented. 4. In all cases the general state of the patient remains satisfactory, the sustained appetite and clear voice proving that there is no serious constitutional affection. 5. If the larynx is attacked, resorcin is not so bene-

ficial; nevertheless, the drug may still be used advantageously by fumigation and atomization if there is sufficient space in the larynx to prevent asphyxia, or if tracheotomy is likely to prove of permanent relief.

Army Medical Board.

An Army Medical Board will be in session in New York City during April, 1891, for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies, numbering now five.

Persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before April 1, 1891, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from whence they were graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character and moral habits. The candidate must be between 21 and 28 years of age, and a graduate from a regular medical college, as evidence of which, his diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing the Surgeon-General U. S. Army, Washington, D. C. C. Sutherland, Surgeon-General U. S. Army.

Quill Drainage-Tubes.

Dr. Otis K. Newell, Surgeon to the Outpatient Department of the Massachusetts General Hospital, Boston, says, in the *Medical Record*, February 7, 1891, that Dr. Beach has used for the past two years, at his clinic, drainage-tubes made from large-sized imported goose-quills, such as are used for making the finer grades of camel's-hair brushes. The quills are taken without cutting off the dermal end, and perforated at intervals with an ordinary round leather punch. As shown in a figure, a delicate and smooth probe-pointed tube is thus provided, presenting the maximum lumen and minimum thickness of wall. This tube is made from a natural dermal appendage and is absolutely unirritating. It can be readily cut with scissors, and is not fragile like glass. It does not undergo any of the irritating chemical changes which are frequently seen where rubber tubes have remained for any length of time. These tubes are preserved in corrosive sublimate or carbolic acid solutions, and are easily sterilized.

Homœopaths Converted.

The *New York Medical Times* (a sort of homœopathic journal), in its issue for February 7, 1891, says: "Dr. Carroll Dunham, son of the late Carroll Dunham, M. D., for a long time Professor of Materia Medica, etc., in the New York Homœopathic Medical College, according to the *Medical Register* of the United States, is a graduate of the said homœopathic college of the year 1880, and of Bellevue Hospital Medical College of 1887, and is registered as a 'regular' physician residing at Irvington, N. Y. We are informed that Dr. E. K. Dunham, another son of the late Dr. Carroll Dunham, is also a 'regular' physician! We are told that several sons of the late Dr. Berens, a homœopathic physician of Philadelphia, are in the 'regular' school! The list could be extended! It certainly looks as if these gentlemen were not satisfied that homœopathic colleges in general teach the whole of medicine."

OBITUARY.

CHARLES WALTER, M. D.

On Thursday, February 12, 1891, Dr. Charles Walter died of pneumonia, after an illness of three days, at the premature age of twenty-five years. Dr. Walter was graduated from the Medical Department of the University of Pennsylvania, in 1888, and was elected one of the resident physicians to the Philadelphia Hospital, serving from August, 1888, until early in January, 1890, when he was elected permanent resident physician in the Insane Department, which position he held until the time of his death.

By his associates, to whom his untimely death will prove a severe blow, Dr. Walter was held in high esteem for his earnestness, his conscientiousness and his fidelity to duty.

But a few days ago, his assiduity was the means of saving a young life hovering at the point of death.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (Absolutely Harmless.)

Is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT, AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. E. R. Squibb, of Brooklyn, writes as follows in an article headed "On the Medical Uses of Hydrogen Peroxide (*Gaillard's Medical Journal*, March, 1889, p. 267), read before the Kings County Medical Association, February 5, 1889:

"Throughout the discussion upon diphtheria very little has been said of the use of the Peroxide of Hydrogen, or hydrogen dioxide; yet it is perhaps the most powerful of all disinfectants and antiseptics, acting both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. The few physicians who have used it in such diseases as diphtheria, scarlatina, small-pox, and upon all diseased surfaces, whether of skin or mucous membrane, have uniformly spoken well of it so far as this writer knows, and perhaps the reason why it is not more used is that it is so little known and its nature and action so little understood. . . . Now, if diphtheria be at first a local disease, and be auto-infectious; that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and a sufficiently repeated contact. . . . A child's nostrils, pharynx and mouth may be flooded every two or three hours, or oftener, from a proper spray apparatus with a two volume solution without force, and with very little discomfort; and any solution which finds its way into the larynx or stomach is beneficial rather than harmful, and thus the effect of corrosive sublimate is obtained without its risks or dangers. . . ."

Further on Dr. Squibb mentions that CHARLES MARCHAND is one of the oldest and best makers of Peroxide of Hydrogen, and one who supplies it to all parts of the country.

CAUTION.—By specifying in your prescriptions "Ch. Marchand's Peroxide of Hydrogen (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

A book containing full explanations concerning the therapeutical applications of both CH. MARCHAND'S PEROXIDE OF HYDROGEN (Medicinal) and GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

Laboratory, 10 West Fourth Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{10}$ gr.), Atropiæ Sulph. ($\frac{1}{500}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. $\frac{1}{10}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{10}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

88 Maiden Lane, **New York City.**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

SUPPLEMENT TO THE MEDICAL AND SURGICAL REPORTER, FEBRUARY 28, 1891.

Suggestions for the Treatment of Tuberculosis.

After the sheets for the REPORTER of February 28 were printed, the following communication was received from Prof. Samuel G. Dixon.

TO THE EDITOR—*Sir*:—As I have never felt sufficient confidence against the toxic effect produced by subcutaneous injections of de-vitalized tubercle bacilli upon the animal economy suffering with tuberculosis, to risk its use in man, I have been using, for some time past, as stated in former communications, a long line of other agents, and I believe that it is only right and proper for me to again call attention of all workers in bacteriological investigation to what I have before strongly hinted at, when alluding to the effects of food, light, temperature, etc., upon the growth of the tubercle bacillus on an artificial culture pabulum.

Glycerine is one of the substances that I have employed in excess since 1889, as specially mentioned in previous articles, and with a marked effect on the growth of the tubercle bacillus.

After satisfying myself that I had pretty clearly established the effect of an excess of glycerine in the nutritive Agar-agar glycerine medium upon the growth of the organisms, I went on to introduce large doses subcutaneously into the animal economy, where a tuberculous process was going on.

In the few cases thus treated, there has, to all appearances, been produced a marked change in the tuberculous process in the animals. Therefore, to facilitate matters, I hasten to place before my colleagues the suggestion indicated above, and I should be very glad if they would themselves try its action in the animal economy, and report their observations.

Yours truly,

SAMUEL G. DIXON, M. D.

Bacteriological Laboratory, Academy of Natural Science, Philadelphia.

Liebreich's Remedy for Tuberculosis.

The cable brings news, dated February 25, that Prof. Liebreich had, on that day, described a new method of treating tuberculosis at a meeting of the Berlin Medical Society. The substance used is cantharidate of potash, which is administered in solution by systematic injections under the skin. Clinical experiments made by Drs. Fraenkel and Hermann seem to prove that the substance is remedial in tuberculosis and other diseases. Prof. Liebreich says that he is still carrying on his investigations, and that the announcement of his discovery was made prematurely, under pressure from Minister von Gossler, who is giving the matter much attention.

CLINICAL LECTURE.

NERVOUS DYSPEPSIA.—CHRONIC DYSENTERY.—MOIST GANGRENE.—FACIAL PARALYSIS.[1]

BY DR. ROBERT COLTMAN, JR.,

TUNG CHOW FU, CHINA.

Nervous Dyspepsia.

This man, 51 years old, is a physician who is practicing, without a diploma, a mixed system, embracing the humbugs of native origin and to some extent the science of Western medicine. His history is as follows. He has always lived a temperate life, has never been seriously ill, and has never had syphilis. Last August, during the cholera epidemic, he had a great run of cases, including his wife. Many of the patients died, and his wife, after an illness of three days, also perished. To loss of sleep, fright and grief, he attributes his present trouble. He is tall, slender and looks anemic. He says he sleeps poorly, and that his appetite is capricious and usually poor. His bowels are regular, but the stools are dry and somewhat scanty. He has a cough without expectoration. His tongue is large, thick and moist, but heavily coated with a whitish yellow fur. His pulse is irregular and intermits, losing on an average four beats per minute—that is to say, it drops out completely four beats. He tells us he has doctored himself for three months, and has got steadily worse, and now feels himself physically and mentally a wreck. He has taken quinine, muriatic acid, capsicum, castor oil, cod-liver oil, pepsin, pyrophosphate of iron, and any number of native drugs, and says he never felt any decided effect except when taking the cod-liver oil, which made him decidedly worse. His lungs are sound, and his heart, although intermittent in action, is also free from disease.

Now what is the matter? and what can we do for him? I reply he has nervous dyspepsia; and, as it is a recent case, we can probably effect a cure. First we want to disabuse the doctor of the idea he has, that his heart is badly diseased and that he is going to die. This we can do with such emphasis that he will readily believe us. Then as to medicines: we shall direct him to take a pill made up as follows:

℞ Ext. nuc. vom . . . . . gr. ¼
Aloes . . . . . gr. i
Myrrh . . . . . gr ss
Ferri sulp. exsiccat . . . . . gr. ss
Pulv. podophylli . . . . . gr. $\frac{1}{16}$
Saponis . . . . . gr. ss
M. ft. pil. i.

To be taken after breakfast and supper. He will also be given a powder containing pulv. digitalis and pulv. quininæ sulp., āā gr. i, three times daily.

Chronic Dysentery.

The second patient is a man 54 years old, a farmer. This case also dates from August last. At that time the patient had a sharp attack of dysentery which was treated by native physicians; and although the violence of the disease abated, he has to this day some symptoms unrelieved. He says he gets along very well through the daytime, but invariably has to have from three to four stools at night, with more or less straining. Sometimes he passes a little blood and mucus with watery feces, and sometimes only mucus. He lives on hard bread, cabbage and millet. His diet is a matter of the greatest importance, for two reasons: First, he is nearly exhausted and cannot much longer sustain this tax on his strength on a vegetable diet; Second, his present diet is directly irritating to the intestinal tract, besides being difficult of digestion. We

[1] Delivered at the Presbyterian Hospital at Tung Chow Fu.

shall direct him to live exclusively on soft boiled rice, eggs—raw or under done—and broiled steak. He is to take a tonic containing a fluid drachm each of compound tincture of cinchona, compound tincture of gentian and tincture of cardamom, in a little water before each meal, and at bedtime a pill containing pulv. opii, gr. iss, and pulv. plumbi acet., gr. ij. Under this treatment we may hope for his restoration to health.

Moist Gangrene.

The next patient is a man 60 years old, a laborer. This poor fellow is in a pitiable plight, and I fear we can do very little for him. He is barely able to answer our questions; his mind seems benumbed, and it takes him some time to realize what we have asked him. The whole dorsal surface of his right foot is about to slough off, and the leg to the knee is infiltrated and swollen. He says four days ago the foot began to pain, and in that time it has reached this condition. I have seen but one or two cases of this nature, but feel sure that it is of the same nature as noma or rapid gangrene of the mouth or cheek. This man has been out of work for some time and starving; his blood has become so degenerate that now I fear the best tonics and alteratives will do him no good. The condition of his mind augurs ill, and I fear that in two or three days at furthest he will have passed away. His pulse is 60, his tongue pale and but slightly coated, but tremulous. He has no dropsy. He has no appetite. His temperature is sub-normal. Although this man walked in here with difficulty, and will be able to walk out, I regard him as in a dying condition, and shall have him placed in the wards. We will give him what seems to be indicated, namely, whiskey, quinine, eggs and beef juice; but the end is not far off.

It is only among the poorest class that such a disease is possible. It may be that syphilis has something to do in starting the ulceration, as it resembles phagedenic action more than anything else I have knowledge of. Amputation would be impossible in his condition. Locally we shall apply a poultice of flaxseed meal sprinkled with iodoform, partly as an antiseptic but principally to cover the odor which is penetrating in the extreme.

Facial Paralysis.

This man, 26 years old, is a school teacher. He comes to us for the second time, saying that he is much better than when he first consulted us some six days ago. At that time, although he strenuously denied that he had syphilis, I diagnosticated his case as facial paralysis due to gumma somewhere along the course of the facial nerve. He had gone to sleep at night apparently healthy, though he had been having more or less headache for a month previously, and awoke in the morning with his mouth all drawn to one side, and with dropping of the eyelid. He consulted us at once, and his rapid improvement is due to the fact that he was seen and treated early. If these cases are left to themselves they seldom manifest a tendency to improve, but go from bad to worse until finally imbecility and death ensues; but, if treated early and vigorously, the prognosis is very favorable, most of the cases making a complete recovery. It is important in these cases to mercurialize the system as rapidly as possible, and to maintain the impression for several weeks, after which the mercury should be exhibited in minute doses intermittently for a year or so. If the stomach is weak or irritable, I use inunction of blue ointment twice daily; but where—as in this case—the man is strong and has a good stomach digestion, I prefer to administer mercury by the mouth. This man has been taking one-eighth grain of corrosive sublimate and ten grains of iodide of potash three times daily. We will now decrease the corrosive sublimate to one-tenth grain per dose and renew his medicine for six days.

I remember a rule of practice taught me in college, which was: In all cases of facial paralysis occurring in a subject under thirty years of age to suspect syphilis. In ten years' practice I have yet to see an exception to this rule for diagnosis.

Dangers of Illuminating Gas.—It has been shown that respiration of the products of the combustion of an Argand burner produces upon animals only deoxygenation, because in this case combustion is complete. It produces only carbonic acid, and not carbonic mon-oxide. If, on the contrary, the combustion of the burner is incomplete, it gives birth to acetylene and a larger quantity of carbonic mon-oxide. Intoxication is rapid in this case. It results from these experiments that it is necessary to remove the products of combustion from ordinary gas burners as well as from gas stoves.

COMMUNICATIONS.

PEROXIDE OF HYDROGEN FOR CLEANING THE HANDS.

BY CHARLES P. NOBLE, M. D.,
SURGEON IN CHARGE OF THE KENSINGTON HOSPITAL FOR WOMEN, PHILADELPHIA.

The remarkable properties of the peroxide of hydrogen as a pus destroyer and as a cleansing agent are becoming better appreciated every day. Every one who uses this agent in the treatment of suppuration becomes enthusiastic in its praises. This being true, time only is required to overcome the prejudice against it which heretofore has existed among the profession as a whole.

I wish at this time to call attention to the use of the peroxide in cleansing the hands. It is a demonstrated fact that it is impossible to render the hands surgically clean, that is, free from septic germs, by the use of soap and water, the nail-brush and corrosive sublimate solutions. Germs still remain under and about the finger nails. It seems more than probable, although I know of no experiments to support the supposition, that germs will find the most secure hiding-place about the finger nails, when the skin has been made rough and thick about the nails, by excessive use of the hands, or by their frequent exposure to irritating fluids, as corrosive sublimate solution. For some months, in preparing for abdominal sections, I have used the peroxide of hydrogen solution in full strength, to assist in cleaning my hands, especially about the finger tips and nails, whenever, for any reason, I have felt doubtful about their aseptic condition. The peroxide has been used whenever the skin about the nails has not been in good condition; and it is remarkable to see how it will soften horny skin at the side of the nail, and disintegrate *débris* in the subungual space, or macerate and even remove epidermic scales. There can be no doubt that foreign material can be removed from the fingers much more completely by using the peroxide solution after using soap and water and the nail brush, than by the use of these agents alone. This certainly does *promote* asepsis. But whether the hands are made aseptic by the peroxide solution I have not been able to determine. Careful bacteriological experiments to determine this question will be of great practical interest and value.

The method which I employ for rendering the hands aseptic is as follows: The nails are trimmed reasonably short, and the subungual spaces are cleared with the knife blade. The hands and forearms are then thoroughly washed in warm water, a good lather being made with soap, and a stiff nail brush being vigorously applied. The water is renewed three times. The hands are next soaked in a saturated solution of permanganate of potassium, and this removed by soaking them in a saturated solution of oxalic acid. According to circumstances, the finger tips are next soaked in peroxide of hydrogen, for the final bath corrosive sublimate solution 1-1,000 is employed. The hands remain in the sublimate solution three minutes. At least ten, and often fifteen minutes are consumed in the cleansing process.

To those who are accustomed to wash the hands quickly, use the nail brush lightly, and to *dip* the hands in the sublimate solution, such elaborate and painstaking care doubtless appears like a useless expenditure of energy. But bacteriological experiments have shown that germs exist about the nails of fingers cleaned in this careful manner (omitting the peroxide solution) and have demonstrated the necessity for some more reliable method of rendering the hands aseptic, if the antiseptic conscience is to be satisfied. It is with the hope that the peroxide of hydrogen solution will meet this demand that I have brought the matter forward.

Aside from using the peroxide solution in preparing the hands for abdominal operations, I have found it perfectly reliable in removing foul odors and stains from the hands, by contact with decomposing pus, discharges from cancer, and other septic fluids. I believe it will be equally useful to the general surgeon and obstetrician.

MEDICAL COLLEGES OF VERMONT.—BOGUS AND GENUINE.

BY JOHN M. CURRIER, M. D.,
NEWPORT, VERMONT.

Just now we are having quite an epidemic of bogus medical colleges in some of the smaller towns of Vermont. Some of these were unknown to the medical profession of Vermont until the Censors of the Vermont Medical Society received letters from the Censors of some of the medical societies of the Western States, inquiring about the standing

of these institutions. The graduates of these institutions settled in the far West, thinking they would never be molested; but now and then they are required to present their credentials to some State Board of Censors, and are thus shown to be possessors of bogus diplomas, and frauds upon the public, and their standing as to medical knowledge and proficiency is brought to light.

For the fair name of the medical profession of Vermont I propose to give a short history of the various medical colleges of the State, both bogus and regular, those that have existed and those now in operation. This history may be of service to practitioners, living in the far West, who are striving to elevate the standard of medical education, and to protect the public from the impositions of uneducated practitioners and charlatans.

Of the four bogus institutions that have actually issued diplomas, only one makes any pretence to delivering lectures or possess any building or room suitable for imparting instruction to a class of medical students. The citizens of those towns in which these institutions purport to be located were not aware of the existence of them until they were exposed by the secular newspapers. Even the members of the regular profession, living in the immediate vicinity, were unaware of their existence. They seem to be carried on by one leading spirit in each case, clustering around him names enough for a Faculty and Board of Trustees. In the majority of instances these names were obtained on some pretence, to act as trustees or officers, without knowing that they were to be connected with a bogus medical college, while the Dean of the faculty was gathering in the profits from the sale of diplomas. Some of these institutions have been exposed by the secular press, when the greater portion of the faculty and trustees learned for the first time that they were at the head of a learned institution; and credit is due to many of them, for immediately appearing in a letter of explanation, disapproving the institutions with which they were unwillingly connected.

I will mention first the four bogus colleges, then the three regular institutions that have been chartered by the Legislature.

Union Medical Institute.

In the *Argus and Patriot*, of Montpelier, under date of November 19, 1890, appears an article quoting from the *Boston Herald* an exposure of "The Union Medical College" of Newbury, Vt. It also adds some comments of its own. The report states that at the session of the Legislature of 1886 a bill was passed by the House incorporating a Homœopathic medical college to be located on the east side of the State; but it was killed in the Senate. Dr. George B. Hatch was said to be prime mover in the scheme. The proposed college failed to obtain legislative sanction, but the scheme was not abandoned by Dr. Hatch, who seems to have determined to do business on his own account, regardless of the State.

Recently, however, a reporter of the *Boston Herald* got hold of what purported to be a catalogue of "The Union Medical College, of Newbury, Vt." This pamphlet was about 4 by 6 inches in size, contained some 16 pages, and was printed by C. E. Caswell, a 17-year-old amateur printer at Warren Summit, N. H., a hamlet of perhaps a dozen houses. Caswell says he printed 300 for $7, but has only received $5 of his pay, although the books were delivered in June, 1889. He says that Hatch, for whom the work was done, suggested that nothing be said about the job. The cover bears the name of the alleged college, as given above. The second page contains the list of Trustees, Officers and Faculty.

The President of the Board of Trustees is Horace W. Bailey, a grocer and Town Clerk of Newbury, a man of good reputation and good business ability, but with none of the requisites usually thought indispensable in the President of a medical college.

The Daily Journal of Montpelier, under date of November 7, 1890, makes further allusion to the matter as follows: The leading spirit in the college is Dr. George B. Hatch. There is no doubt that several of the men whose names are used were deceived as to the nature of the college, for they stand high in their respective communities. The institution has never had a student, nor has it a location at Newbury, so far as we know. The *Herald* says it is the general opinion that diplomas are being sold in the West, and one prominent business man made this statement: "It is susceptible of proof that two diplomas have been sold for $50 apiece."

At a later date appeared the following: H. W. Bailey, of Newbury, who was advertised as the president of the bogus medical college up there, writes a letter that exoner-

ates him from blame. He consented to act as trustee only for a genuine institution, and never consented to the use of his name as president. Dr. G. B. Hatch, the concocter of the thing, claims that no diplomas were ever issued, but that he had an idea of starting such an institution at the Montebello Mineral Spring, got encouragement from a "Southern gentleman" as to capital, and had a few catalogues printed as sort of samples, but allowed only a few copies to go out.

Dr. Hiram A. Cutting, A. M., M. D., Ph. D., of Lunenburgh, is a scholarly man, mostly self-made. For many years he was State Geologist of Vermont, and Secretary of the State Board of Agriculture; and has lectured much at agricultural meetings, and before various colleges. His three degrees are honorary. About this college he writes me: "There is no medical college at Newbury and never has been, to my knowledge. I received a letter something more than a year ago from one Dr. Hatch, of Newbury, saying that a friend of his from the South was talking of purchasing the school property and Medicinal Spring at Newbury and they might get up an institute class, and if such was done, he desired me to give two or three lectures on microscopic work, etc. I wrote him I would try and do so. The next I knew was that the project had fallen through. I have lectured before various colleges upon the microscope, mounting objects and the microscopic advantages in anatomy, etc., but was never president or official board member of any."

It seems that Dr. Hatch, who is not a graduate of a regular school, after the medicinal-spring scheme fell through, turned his attention to the sale of diplomas. Of his capacity for study, a friend writes me: "Dr. Hatch commenced the study of medicine with Dr. E. V. Watkins [of Newbury] some years ago, but did not continue with him in that capacity only about three weeks, when Dr. W. told him that he could never succeed unless he would devote all his time and talents to the study for years, and at that time Hatch gave up the idea of studying medicine, and left for other fields."

Shortly after his return to Newbury this new medical plant came quietly into existence, *sub rosa*. It was full-grown when first discovered. But since its exposure in the newspapers the members of the faculty either keep silent or deny their connection with it.

The exposure of this and other bogus colleges will have the effect to check the immediate sale of diplomas; but as soon as the excitement in the medical profession dies down, traffic will revive with renewed energy. The newspaper exposure will make them more noted, and those who desire to possess diplomas, without regard to standing, have learned where they can be purchased, and avoid hard study. The Legislature of Vermont has done a bad thing, or rather has neglected to do a good thing, for the medical profession of the State, at its recent session. A bill was introduced making the sale of bogus degrees a penal offense; but it failed in its passage. I have been informed that if the bill had been designed simply to prevent the sale of diplomas it would have passed, but it was so framed with other matters that were objectionable that the subject of degrees could not be singled out, so the whole matter was "heaved over among the rubbish," by the disinterested representatives. The outcome of this unwise legislation will be a large crop of bogus diplomas from Vermont for the next two years.

Trinity University.

Under this title the State Censors have received letters from the censors of some of the Western States inquiring into the standing of the institution. No such an institution exists there.

Medical College at Newfane.

I am unable to find the name of the Medical College at Newfane, but inquiries have been made as to its standing, recent graduates having occasion to bring forward their diplomas, and were thus brought to light. No College exists there. It is a small obscure town.

Vermont Medical College.

This concern was located in Rutland about 1883. Dr. George Dutton is the originator and the principal man. It should not be confounded with the Vermont Medical College that existed in Woodstock between 1824 and 1856, which will be reviewed later on in this article. This Rutland plant is located in a room, secured by the Dean for the purpose, of sufficient size to accomodate only a few students. Lectures are delivered annually, but they are superficial, erratic, lacking in method, in

fact, worthless to a student obtaining knowledge for practice. The students are of an inferior grade intellectually. This school claims to be a chartered institution, but it is not. The State of Vermont several years ago, passed an act by which an organization could be formed having privileges similiar to a corporate body, without making direct application to the Legislature. These privileges were, however, somewhat restricted. Under this law the Rutland school was organized, and claimed to be a corporate body. There seems to be nothing hidden about it in its movements, on the contrary, the managers seek publicity and notoriety. They have been defiant and pugnacious, taking advantage in every spot and place to defend the institution from attacks. The past summer they graduated a class; and they took great pains to make a display, all the medical fraternity of the State and the public were invited to attend the graduating exercises. Each graduate read a paper on some medical subject, on the occasion. The reporters of the press were on hand, and some of them published quotations from the medical essays read, which reflected upon graduates unfavorably, and afforded much amusement to the physicians who read the reports.

One of the graduates of the institution desired to settle in the State to practice; but before she could do so, the law required that she must have a certificate of qualification from some Board of Censors of a medical society, recorded in the County Clerk's office. She made application to a Board of Censors for the certificate, and the Board refused it. Suit was brought to constrain the Board to issue a certificate; but the Courts decided against the application.

It has been charged that the school was of a "spiritualistic" nature; but the "*Faculty*" every time came forward with a denial. It has been noticed, however, that Dr. Dutton attends the "spiritual" conventions quite frequently, and distributes circulars and announcements of that school very extensively.

Application was made to the Legislature of Vermont for a charter of the Rutland school, but it was refused in the House of Representatives by almost a unanimous vote. Thus it will be seen, that not only the Courts, but the Legislature also, has set this school down as a bogus institution, and its diplomas are worthless, and a stigma to the possessor.

Castleton Medical College.

In 1881 I prepared a history of the Castleton Medical College for the first volume of the proceedings of the Rutland County Historical Society. From that volume I make such extracts as will be of service to medical censors throughout the United States. I was in possession of the written records of that institution from its origin, and the most complete file of the catalogues of it that was in existence in any library. That institution was chartered on October 29, 1818, as the Castleton Medical Academy. Drs. Selah Gridley and Theodore Woodward, of Castleton, were the real founders. By an Act of the Legislature passed on November 7, 1822, the name was changed to the Vermont Academy of Medicine. By an Act of the Legislature, November 1, 1841, the name was again changed to Castleton Medical College. The first course of medical lectures was delivered in the winter of 1818–19; the last course was delivered in the spring of 1861. The war of 1861–5 put an end to its existence. There were no lectures delivered in 1838 and 1839. Up to and including 1827, degrees were conferred upon the graduates under the auspices of Middlebury College. After that date diplomas were issued by the faculty of the college independently of Middlebury College. Many eminent physicians graduated from this college, and all were in good standing in the profession. Many of the graduates are still in active practice.

Vermont Medical College.

This institution was started through the influence of Dr. Joseph A. Gallup, at Woodstock. The first course of lectures was given in the autumn of 1827. It received the name of the Clinical School of Medicine. For three years the graduates received their degrees from Waterville College, in the State of Maine. In 1830, a connection was formed between that institution and Middlebury College, from which the graduates received their degrees until 1836. In October, 1835, the Legislature of Vermont granted a charter to the Woodstock school under the name of the Vermont Medical College, with authority to grant diplomas to its graduates. Lectures were given annually in the spring, until 1856, when the last course was delivered; and its existence ceased then. The graduates of this institution stood well in

the profession, and some became eminent as medical teachers in other schools.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF VERMONT.

This is the only college in Vermont that now delivers medical lectures and issues diplomas to any medical graduates. It is in a flourishing condition and is careful to graduate only those found to be competent to practice. In the autumn of 1822, the first full course of medical lectures was delivered. These lectures were continued annually up to 1833, when they were suspended. In 1854, the department was again revived, and it has continued to increase up to the present time.

The three last-named colleges are the only ones that have been authorized to grant diplomas in the State of Vermont. All other before mentioned are bogus.

GENERAL ANTISEPTIC MEDICATION.[1]

BY H. F. SLIFER,

NORTH WALES, PA.

I desire to bestow some consideration to the subject of general antiseptic medication. It is my object to present to the Society the use of antiseptics in general practice, not confining my remarks to antiseptic surgery, which I regard as only a part of the antiseptic treatment.

Sepsis is that morbid condition produced by the absorption of toxic matter into the tissues or blood. Three primary factors are engaged in the production of this pathological condition: 1. Micro-organisms; 2. Ptomaines; 3. Leucomaines.

The recognition of micro-organisms as the essential cause of specific disease, supplies a scientific basis for diagnosis, and affords a definite principle by which we are enabled to test methods of treatment. The existence of putrid fermentation, taking place in the tissues of the body, is proved by the following evidence: 1. The presence of certain micro-organisms; 2. Certain cadaveric alkaloids—ptomaines, the product of putrefaction; 3. Certain special products—leucomaines, which originate in the living tissue as a result of retrograde metamorphosis. These are divided into two groups: the uric acid group, and the creatinine group.

It has been seen that it is not the organisms themselves that are the irritants that directly cause disease, but the products that are formed in the course of their growth and multiplication, either directly secreted by them or formed by the decomposition of the substances on which they feed. From these facts we can draw this important conclusion: That man in the physiological state produces poisons, more or less virulent, the true nature of which we do not as yet understand, and that the condition of health for him consists in their regular and rapid elimination by the different emunctories, and especially by the skin, the kidneys and the intestines; nor must we omit to mention that colossal eliminator of impurities, the liver, which has for its function the destroying of a certain number of these toxic alkaloids. But let some circumstance come to interrupt this equilibrium, let the skin close its life-giving gates; let the liver cease its function; let the glomeruli of the kidneys become obliterated; let too active an absorption take place from the intestines, whether by abnormal shedding of its epithelium, or by the presence of ulcerations, or by want of power on the part of the digestive ferment sufficiently to prevent the production of putridity and fermentation, and then may ensue a pathological condition which we will term sepsis.

The agents with which we antagonize and destroy the above enumerated toxic products are termed antiseptics. This system of medication is destined to have a high place in the therapeutics of the future, and should be studied and practiced by every physician and surgeon. I propose to make some practical application of this method in diseases as we meet them in general practice.

In the different forms of stomatitis, it is of primary importance to maintain perfect cleanliness, by keeping the teeth well brushed and by frequent washing of the mouth, especially after taking food. The most effective washes for this purpose are: boric acid, carbolic acid, chlorinated water, solution of permanganate of potassium, bicarbonate of soda, and creoline. When the gums are tender and disposed to bleed, astringents are indicated. If ulceration is present, the mouth should be washed as above indicated, and the ulcer dusted with iodoform, charcoal, or boric acid; or a lotion of carbolic acid, sulphate of copper (two grains to the

[1] Read before Montgomery County Medical Society.

ounce), or nitrate of silver (five grains to the ounce), chlorate of potassium or bichlorate of mercury (2 to 1,000) should be applied.

In diphtheria we have a local as well as a constitutional pathological condition presented, in which the antiseptic treatment is especially applicable, and this, if properly carried out, will produce excellent results. In mild cases I use the inhalation of steam and lime, or steam and carbolic acid, alternating with a gargle of chlorate of potassium or borate of soda. In cases of graver import, I use medicated steam with a gargle of bichlorate of mercury (2 to 1,000), bromide of potassium, or bicarbonate of sodium with alcohol or whiskey, from which I have had excellent results. Recently, I have used sulpho-calcine with great satisfaction. The direct application of this drug on cotton, or with a camel's-hair brush, or as a spray, in its concentrated form, will often remove or dissolve the membrane. The use of iodoform, mineral acids and vegetable astringents has failed in my hands.

In the nasal complications, the injections should be made every four hours or oftener if necessary; at the same time it is advisable to be careful that the fluid does not enter the Eustachian tubes. This can be prevented, to a certain extent, by compelling the patient to keep the mouth open during the operation. In selecting the drug for this purpose, it is well to avoid those which stain or produce a firm coagulum. For this reason I employ carbolic acid, bicarbonate of sodium, borate of sodium and bichloride of mercury.

Prof. Alfred L. Loomis speaks highly of the benzoate of soda, to neutralize the diphtheritic poison. Dr. Geo. B. Fowler considers calomel the best remedy with which to combat this terrible malady. Dr. A. Jacobi advocates turpentine. Dr. J. Solis Cohen regards the chlorine compounds as of more efficacy in diphtheria than all other remedies.

I have had no personal experience with benzoate of soda, calomel and turpentine in diphtheria; but coming from such eminent authority, I am inclined to give them a test as soon as an opportunity will present.

The efficacy of antiseptic treatment, in diseases of the stomach, depends materially upon the manner in which it is executed; the more thoroughly the stomach is washed out, the greater will be the success. In dyspepsia and chronic gastritis the following drugs are indicated: carbolic acid, salicylate of bismuth, subnitrate of bismuth, salol, iodoform, charcoal, carbon bisulphide water, and hydrochloric acid. In gastric ulcers, charcoal, small doses of calomel and nitrate of silver are the most efficacious remedies. The food and drink must be boiled or sterilized, and selected with especial care, and adapted to the peculiarity of each case.

Dr. Bouchard has the credit of first attempting intestinal antisepsis. He treated his typhoid fever patients with a mixture of charcoal and iodoform, and naphthol in large doses. Dr. Dujardin-Beaumetz, is perhaps one of the strongest advocates of this form of intestinal treatment. He says: "The physician can, and ought to interfere, to combat these intestinal septicemias, and he attains this end in employing two kinds of drugs: one kind which has for its object to prevent putrid fermentations from developing in the digestive tube, and to destroy the toxic elements which are formed there; another which has for its end the favoring of the rapid elimination of this matter from the intestines. Let us examine each of these indications, and the indications designed to fulfil them, commencing with the last. The indication to eliminate the toxic matter found in the digestive tube, and to favor their speedy issue, is fulfiled by purgation. Medical agents which are capable of modifying the putridity of intestinal matter, we find may be introduced by two channels: either directly into the intestines by means of enemata, or indirectly by the mouth. The antiseptic substances which can be used by enemata are not very numerous, on account of their irritant and toxic action. To avoid this, we are obliged to employ substances which are but slightly irritating and toxic, such as salicylic acid, boric acid, cupric sulphate.

"These injections have no toxic effect and they disinfect perfectly the contents of the large intestine. Their action is, however, local, and you should endeavor to medicate the entire intestinal tract; and for this purpose substances should be introduced by the mouth. Among the drugs worthy of being advised for this object, there are three to which I desire to call attention, namely, charcoal, iodoform and carbon bi-sulphide water."

Dujardin-Beaumetz also speaks in high terms of salicylate of bismuth, associated

with magnesia or bicarbonate of soda, with naphthal or salol in diarrhœa.

It is evident, that the best results are to be realized from drugs that are slightly soluble. Only insoluble drugs can be depended upon to reach the lower part of the intestines. In diarrhœa in which the putrefactive processes are marked, as indicated by flatulence and offensive stools, I have had good results from the use of salicylate of bismuth, charcoal, iodoform and salol; in other cases carbon-bisulphide acted more promptly.

In cholera infantum, the antiseptic treatment consists in: 1. Unloading the bowels. 2. Feeding the child on sterilized food; and 3. Antiseptic drugs. I use one of the bismuth salts, or sulpho-carbonate of zinc, iodoform, or small doses of calomel.

In chronic diarrhœa antiseptics are of very little avail, indeed they have proved unsatisfactory.

Dr. Lemoine, of Algiers, has treated fifty-four cases of dysentery with enemata of corrosive sublimate, with the happiest results. The strength of the solution was one to five thousand, of which two hundred grams were at first administered three times a day. In acute cases, a cure resulted from this treatment in from three to four days; in no case was there any sign of systemic poisoning. In view of the infectious character of dysentery, this treatment is eminently rational, and the demonstration that our most powerful germicide can be used with impunity as an intestinal antiseptic is of decided value.

The antiseptic treatment of phthisis has thus far been unsatisfactory. The higher authorities do not recommend it. All that we can reasonably expect from antiseptic inhalations, is that they may decrease the infective power of the secretions and counteract the offensive odor of the breath and expiration.

It is in obstetrics that the antiseptic method of treatment is especially indicated. The Chicago Medico-Legal Society recently discussed the question: "Whether the failure of a physician to accept and practice the precepts of antiseptic midwifery should make him legally liable and responsible if puerperal fever develops in his puerperal patient during his attendance upon her." It seems to me that the obstetrician is in a high degree responsible for unfortunate results. We find, on examining statistics, that the mortality of puerperal diseases has greatly decreased since the institution of the antiseptic treatment.

Dr. William T. Lusk reports in the *Medical News*: "The number of deaths from puerperal sepsis, between the years 1867 and 1875, in New York City, was 1,947, or an annual average of 215." This is the result under the old system. In the same article, Dr. Lusk says: "During the past five years there have been 837 women confined in the Bellevue Hospital, and there have been sixteen deaths, two of which were due to puerperal fever." These figures most emphatically show the value of the antiseptic principle.

In the address on obstetrics before the last meeting of the American Medical Association, the following statement was made: "There are a few simple rules pertaining to the subject of aseptic midwifery, and they must be scrupulously and delicately adhered to by every physician who practices the obstetric art. Failure to do this is to shoulder an awful responsibility, and the consequences of such neglect would be indefensible, either in a court of morals or of law."

It behooves us, therefore, as general practitioners, to exercise every precaution, and to utilize every means at our command to prevent sepsis.

This happy end we attain in two ways. First, asepsis; second, antisepsis. Asepsis we secure by scrupulous cleanliness—not æsthetic, but chemical cleanliness on the part of physician, nurse and patient. The clothing of the physician and nurse should be perfectly clean and free from contaminated air imbibed from the dead-house, or hospital wards, or the rooms of patients in which diphtheria, erysipelas, septic wounds, or the eruptive fevers are being treated. The hands and fore-arms should be washed with hot water and soap, then in an antiseptic solution; and special attention should be given to the finger-nails. The patient must also undergo a cleansing preparation, the abdomen, the thighs, the labia and the anus must be thoroughly washed with soap and water, and finally, with an antiseptic solution—alcohol or bichlorate of mercury.

Antisepsis is secured by the introduction of agents that destroy the toxic matter, and remove the devitalized substances, and those prone to decomposition. These agents are indicated after abortion as well as after labor.

If the labor is perfectly normal, and there is no danger of sepsis, I use one injection

daily of the bichloride solution (1 to 5,000), or carbolic acid (1 per cent.), or chlorinated soda, or permanganate of potash.

In case of any operation, such as version, the application of forceps, or any manipulation by means of which air is admitted, the douche of sublimate solution must be used. The parts are dusted with iodoform and covered with a piece of gauze wet with 1 to 5,000 bichloride solution, or carbolic acid solution, or chlorinated soda.

In surgery we more clearly attain the ideal excellence of antiseptic treatment than in any other department. There we are enabled to apply the antiseptic agents directly to the seat of infection, and to destroy the toxic influence and restore the parts to an aseptic condition. All operations should be performed with the strictest antiseptic precautions. The region to be operated on is cleansed with soap and water, ether or turpentine, and carbolized water (3 per cent.), or bichloride of mercury (1 to 1,000) and is then covered with a towel saturated with bichloride solution until ready. The instruments are sterilized by exposure to steam, or by being placed in boiling water, and are then laid in a 3 per cent. carbolic acid solution. During the operation the instruments, when not in use, should be placed in carbolic solution, or on a towel saturated with sublimate solution. The same precautionary measures must be taken with needles, sponges, etc. The hands of the operator should be washed with soap and water, and alcohol or turpentine, and then with bichloride solution, care being taken that the nails are chemically clean. The operation being completed, the bleeding vessels are secured with carbolized ligatures, or those prepared in oil of juniper, which have been in the bichloride solution for twenty minutes. The wound is now irrigated with bichloride solution. The edges are adjusted, and secured with sutures. The cavity of the wound is again irrigated with an antiseptic solution. The wound is then freely dusted with iodoform, followed with a layer of cotton, saturated with a solution of carbolic acid or the bichloride. This in turn is covered with two or three layers of antiseptic gauze. This may be covered with oiled silk, or oiled muslin, or oiled paper, or rubber tissue. Over this a layer of antiseptic cotton is placed, and then the roller bandage. If no discharge or bleeding is perceptible, this dressing can remain for a week without redressing.

It has been asserted that antisepsis could not be carried out in general practice. This I regard as an error. Since the method has been so much simplified, the cumbersome spray apparatus has been abandoned, and the complicated dressings have been discarded, we are enabled to practice it under all conditions and circumstances, let us therefore, bear in mind the principle of the antiseptic treatment, and do the best we can with the means at our command.

VESICULAR ERUPTION IN SCARLATINA.[1]

BY F. C. CURTIS, M. D.,
ALBANY, NEW YORK.

The importance of any unusual deviation from the ordinary character of the eruption in one of the exanthemata calls for its report and record. The following is the report of a case of scarlatina, in which a vesicular eruption developed.

The patient was a stout, well-developed child, four years of age, of German parentage, and the youngest of a family of several children. On November 29, after having been perfectly well all day, he was taken suddenly towards evening with vomiting, fever, and, later, diarrhœa. The next morning a scarlatinal eruption appeared, which became well marked and presented no unusual characteristics during that or the two succeeding days. At the request of his attending physician, Dr. William Hailes, I saw him in the evening of December 3, the fourth day of sickness. He was having scarlatina of moderate severity; his pulse was rapid; his tongue had the red, strawberry appearance; the throat was congested. His face was clear of eruption, and on the chin and neck was beginning to peel. The body and limbs were covered with a deep scarlatinal eruption, fading on deep pressure except at punctate points, the color returning slowly. The abdomen was covered thickly with petechial, pin-head sized, acuminated vesicles, closely set so as to impart a rough feeling to the touch, and of a whitish color. Similar vesicles covered the inside of the thighs, but less thickly set. A few scattered vesicles were on the chest, none on the back, neck or face. On the

[1] Presented at the meeting of the Medical Society of the State of New York, February 3, 1891.

arms there were a few here and there, but about the elbows they were more numerous. On the wrists and back of the hands, however, there were vesicles differing much from those on other parts in regard to their size; they were large, about the size of a split pea, many were of irregular outline as if formed by the confluence of several vesicles; they were flat, superficial, and their contents were turbid and whitish as if semi-purulent. They involved about one-half of the area of tissue of these parts. At first glance they presented much the appearance of small-pox on the fourth day of eruption; they were lacking in a solid raised edge of a vesicular papule and were not acuminated. This new eruption had developed without apparent accession of fever.

December 4. The vesicles on the abdomen and thighs had not developed beyond this pin-head size, and extended over no greater area. The skin covering the knees had the large flat turbid vesicles found the day before on the wrists, and they were thickly set. Those on the wrists were unchanged, but had extended up the ulnar side of the arms. They appeared to cause no inconvenience to the child. The body was still quite red.

December 5. On the abdomen the vesicles had almost entirely disappeared by absorption, and at their sites were scales yet adherent. About half of the vesicles on the hands and arms had disappeared by absorption. None had been ruptured or torn by scratching. On the knees the vesiculation was still active. The vesicles of the knees and wrists had appeared upon the ankles, and were quite similar in every way. Between joints there were only few vesicles. The redness of the entire body was fading, and there was but moderate febrile action.

December 9, four days later, the child was up and dressed. The vesicular eruption had entirely disappeared, and at the sites of the large and profuse vesiculation the cuticle was peeling actively in large, thin flakes, aside from which there was no mark to indicate their former existence, they having entirely disappeared by absorption. A more furfuraceous exfoliation was going on over the covered parts of the body. The tongue was still red and showed elevated papillæ, and the fauces were still congested. The child subsequently made a perfect recovery without accident, and there were no other cases of scarlatina in the family.

Pathologically, the eruption of scarlatina is a dermatitis. While the efflorescence is due to general engorgement of the cutaneous vessels, there is always a larger degree of engorgement of the capillary loops in the papillæ of the derma, producing the pin-head sized reddish points seen at the commencement of the eruption and the small, red points which often cover the blanched spot remaining after pressure upon the scarlatinous skin at its height. Sometimes these papillæ are so congested as to impart a rough sensation to the touch. The production of vesicles may be accounted for in pursuance of this pathological process, the engorgement of the papillary capillaries being such that relief may be found, just as in other conditions of dermatitis, by escape of serum and the formation of a vesicle. It would appear that lymphoid corpuscles also escape and produce the whitish appearance that is noted. This would better satisfy the conditions, apparently, than that they are produced as a miliaria, occurring in any febrile condition from follicular inflammation, the sudamina of fever or the prickly heat of hot weather. It is exactly in keeping with the production of scarlatina hemorrhagica, where minute points of reddish-brown color, not obliterated by pressure, develop from escape of blood-globules from the congested papillary capillaries. The occurrence of the vesicles at parts where the dermatitis is most intense, and the whitish appearance of their contents, add force, in a case such as that reported, to this pathogeny.

The literature of this anomaly of scarlatina is scant. It is not detailed with that completeness which would be looked for in consideration of its importance, for while it is referred to very casually as a possibility by Robinson, Hebra, Meigs and Pepper and Bussey, in Keating's *Cyclopedia*, by which author a miliaria eruption is referred to casually, by many writers even of elaborate and compendious articles it obtains no notice. Its importance as a possible occurrence in a common exanthem, usually regarded as altogether an efflorescence, should be recognized and made familiar to the profession.

17 Washington Avenue.

—It is said that the unpleasant symptoms sometimes associated with the continued use of iodine may be prevented by the daily administration of fifteen grains of bicarbonate of soda.

PERISCOPE.

Life-Saving Methods in Still-Births.

At a meeting of the Section on Pediatrics of the New York Academy of Medicine, December 4, 1890, Dr. William T. Lusk read a paper in which he said that a few weeks ago he had been called to the bedside of a primipara in labor. The child's head was low in the pelvis, but for two hours there had been no progress. Extraction of the head by the forceps was easily accomplished, but the cord was found tight around the neck. It was divided with scissors, and the body was extracted. The child, however, had become asphyxiated, respiration had ceased, the heart-beat was scarcely perceptible. He placed the child upon a table, wrapped in warm cloths, expelled the mucus from the posterior fauces, passed a No. 8 English catheter into the trachea, and removed mucus by suction. The quantity of mucus in the bronchial tubes was large, and the catheter had to be introduced many times. Direct inflation was then practiced, and in ten minutes slight heart movements were observed, but these ceased again, and life-saving methods had to be continued for nearly three hours before respiratory movements were finally established. These methods consisted in removal of mucus from the bronchi, inflation through the catheter, warm-water baths with sprinkling of the epigastrium with cold water, and the use of Schultze's and Sylvester's methods alternately. Before using Sylvester's method it had been necessary to draw the tongue forward and depress the base. The next day the child had spasms, but recovered after twenty-four hours, and remains to-day robust and the joy of a family.

He would grant that the story was a familiar one, but its importance led him to bring the subject before the Academy on this occasion. According to his observation, the method usually pursued was to spank the child, wrap it in warm cloths, or dip it alternately in warm and cold water, and lay it away to die. But to manage these cases successfully required perseverance and a knowledge of the physiological laws involved.

It was known that during the period of gestation the child remained in a state of apnœa; that the respiratory function was performed by the placenta. But as soon as the child was born, in normal cases, the thorax expanded, the diaphragm contracted, pulmonary respiration was established. The premature establishing of pulmonary respiration while the child was still in the passages was followed by asphyxia, and was generally the cause of still-births. The author here mentioned the two prevailing theories regarding the cause of respiration taking place at birth, and also cited the experiments of Engstok made on guinea-pigs and other animals, which demonstrated that fetal respirations were excited in the absence of external sources of irritation so soon as the blood in the umbilical veins became darkened or was cut off from the fetus. Peripheral stimuli, however, were capable of exciting the respiratory act before the internal stimuli had increased sufficiently to induce independent action.

After describing the fetal circulation, Dr. Lusk said that, owing to the less amount of blood supplied through the placenta during contractions of the uterus before birth, the respiratory centre in the medulla received less arterialized blood, became more irritable, and this, with the friction upon the body of the child as it passed through the genital tract and came in contact with the air, caused the first respiratory act to take place. This was accompanied by expansion of the chest, opening up of the pulmonary air-cells and of the blood-channels distributed to the lungs, which before had been nearly closed. The blood, therefore, which had before passed from the right ventricle directly to the aorta, was now directed to the lungs. This caused diminution in blood-pressure in all the vessels of the body, the pressure being partially compensated for by aspiration in the vena cava with the acts of respiration. Since the blood, after respiration had set in, was most diminished in the ductus arteriosus, this channel soon became obliterated. In the regular channels the diminished pressure was most marked at a distance from the heart. It was particularly noticeable in the umbilical arteries, the pulsation here often being scarcely perceptible after the child had breathed a few times.

In cases of asphyxia it was somewhat different. In nearly all cases of asphyxia after birth the child had breathed in utero. Intra-uterine respiration was due to tetanic contractions of the uterus, a condition oftener seen when it was more common to give ergot before birth of the child; to premature death of the mother; but oftenest of all, to pressure upon the cord. Cutting off the

blood suddenly from the placenta caused a backward coupe and increased arterial tension, together with an increased amount of work thrown upon the right side of the heart. Intra-uterine respiration taking place, the lung expanded, amniotic fluid, meconium, epithelium, and mucus entered the nose and throat, and, if the efforts at inspiration had been active, even reached the trachea and bronchi. As the respiratory attempt went on, but no oxygen reached the medulla, it gradually lost its irritability, respiration ceased, and the heart and vessels were left engorged with blood. Ecchymoses, if not hemorrhages, were seen in different parts of the autopsy. The time during which the asphyxia had existed, or its degree, differed in different cases. In the milder ones the muscular tone was preserved, the head did not drop, the skin was dusky red or cyanotic, the conjunctivæ were congested, the umbilical vessels distended, reflex movements could be excited by irritation. In these cases respiration often returned. But in the more advanced state of asphyxia the surface was pale, cold, the heart-beat was feeble and infrequent, the umbilical vessels were nearly empty, the head dropped, there was loss of muscular tone; if there was any attempt at respiration there were no associated movements of the muscles of the face.

The first signs of returning animation were the refilling of the capillaries and of muscular tonicity.

The indications for treatment were to clear out the air-passages, restore the irritability of the medulla, increase the force of the heart-contractions, relieve the plethora of the heart and blood-channels, expand the thorax. Where muscular tonicity was still present these conditions were easily fulfilled; and clearing out the fauces and nose of mucus, the use of flagellations and the stimulus of warm and cold water were likely to prove sufficient. But in a number of instances the skin in a few days became dusky, the heart-action feeble, and the child died of atelectasis. To avoid this no method excelled Schultze's.

Schultze's method was illustrated on the child cadaver. The thumbs were placed upon the anterior portion of the child's head, the index-finger in the armpits, the hands diagonally over the back, the body hanging down. The mouth being open, the pulling upward on the thoracic muscles drew the upper ribs upward, while the attachment of the abdominal muscles caused the lower ribs to be drawn downward, the diaphragm fell downward, and thus the cavity of the chest was expanded to the greatest possible degree. Inspiration was thus induced. Now, by extending the hands horizontally and giving the body of the child a forward turn, the position was assumed in which the abdominal viscera pushed up the diaphragm, the ribs were brought in close contact with each other, and the most efficient form of expiration was carried out. Perhaps there was no other way in which the mucosities taken up into the lungs could be so efficiently expelled. Before laying the child aside it was desirable to swing it gently a few times forward and upward over the hands so as to completely ventilate the lungs and expel the mucus from the air-passages. But the greatest advantage of the Schultze method related to the manner in which the congested heart-cavities, thorax and blood-vessels were unloaded of engorged blood. There was no doubt but what the Schultze method would save many of that class of cases which heretofore had been resuscitated only to die the third or fourth day.

But the method was capable of abuse. Before it was employed, the child should be placed in warm cloths, and its nose and fauces cleared of mucus. Then proceed to clear the trachea and bronchi by passing a No. 8 English catheter and using suction. This often required time and repeated introduction of the elastic tube. Meanwhile, insufflations should be employed at intervals. Gentle compression of the chest-wall should now and then be practiced. By these means, little by little, the blood received oxygen, and returning irritability of the medulla was manifested by occasional movements. Then Sylvester's method was practiced. It was not of much use, however, unless one had an assistant to hold the extremities. The tongue should be drawn forward and its base depressed, to permit entrance of air. As soon as the heart-movements became plainly perceptible the child should be placed in warm water, lifted again, and sprinkled with cold water. But to dip it suddenly in cold water had often caused instantaneous death. Putting it into warm water and sprinkling the face with cold water was harmless. Finally, the swinging method of Schultze should be employed, especially for its effects upon the circulation. It should be remembered that cases of asphyxia required watchfulness and

a hopeful spirit. Even after having presumably resuscitated the child by the procedure just outlined, it might again be necessary to go back to the catheter and insufflation.

Homœopathy by a Homœopath.

Dr. W. M. Decker, of Kingston, N. Y., in the *New York Medical Times*, February, 1891, has a paper in which he quotes criticisms of a Dr. Tooker on some resolutions, which Dr. Decker submitted to the Homœopathic Medical Society of the State of New York, at its semi-annual meeting held at Brooklyn last year.

The first resolution proposed by Dr. Decker reads as follows: "*Resolved*, That, in the opinion of this society, the theory of the psoric origin of chronic diseases, as set forth by Hahnemann in the *Organon* and in his other writings, is erroneous; and, therefore, as a basis for treatment, it is misleading."

The second resolution is "*Resolved*, That all symptoms attributed to provings with high potencies are of doubtful reliability; and, therefore, they are not trustworthy guides in practice."

Of this resolution Dr. Tooker says: "The second resolution is only worthy of consideration because Hahnemann in his dotage and some of his disciples in their early enthusiasm believed it and taught it. As the great majority of the followers of Hahnemann, however, at the present day, have seen its fallacy and have already discarded it, there seems to be no special harm in giving it official and respectful burial in the resolution as formulated."

Dr. Decker says he cannot understand how he can accept the one and reject the other. If he is not a believer in high potencies, then, he cannot accept the doctrine of potentiation or dynamization; and that is all the third resolution condemns.

The third resolution is "*Resolved*, That, in the opinion of this society, the theory of potentiation of drugs, as taught by Hahnemann in the *Organon* and in his other writings, that is, the doctrine that the more drugs are attenuated by successive triturations, or the more they are diluted and succussed, the more their power and effectiveness is increased, is hereby declared unsound and unreasonable in principle, except the fact that division of drug matter is accomplished."

This is the resolution which Dr. Tooker cannot accept; and yet he does indirectly accept it, as before stated. The above resolution does not reject attenuation or dilution of drugs. The divisibility of matter is embodied in the resolution as an exception. The resolution does not declare that unsound and unreasonable; but only the doctrine of potentiation. Dr. Tooker seems to lose sight of the distinction between the meaning of the terms attenuation and dilution as compared with potentiation and dynamization when applied to drugs. They are not synonymous terms, and cannot be used interchangeably.

After explaining his notions, Dr. Decker says: "To prove that potentiation of drugs as taught by Hahnemann is false, absurd and unreasonable, I need only refer you to Hahnemann's own statements, viewed in the light of our present knowledge. I refer you to *Hahnemann's Lesser Writings*, by Dr. Dudgeon, p. 733, from which we quote the following: 'In the same way liquid medicines do not become, by their greater and greater attenuation, weaker in power, but always more potent and penetrating. For homœopathic purposes this dilution is performed by well shaking a drop of the medicine with a hundred drops of a non-medicinal fluid; from the bottle so shaken a drop is taken and shaken up in the same manner with another hundred drops of unmedicated fluid, and so on. This result, so incomprehensible to the man of figures, goes so far that we must set bounds to the succussion process, in order that the degree of attenuation be not over-balanced by the increased potency of the medicine, and in that way the highest attenuation become too active. If we wish, for example, to attenuate a drop of the juice of *sundew*[1] to the decillionth, but shake each of the bottles with twenty or more succussions from a powerful arm, in the hand of which the bottle is held, in that case this medicine, which I have discovered to be the specific remedy for the frightful epidemic *whooping-cough* of children, will have become so powerful in the fifteenth attenuation (spiritualization) that a drop of it given in a teaspoonful of water would endanger the life of such a child; whereas, if each dilution bottle were shaken but twice (with two strokes of the arm) and prepared in this manner up to the decillionth attenuation, a sugar globule the size of a poppy

[1] *Drosera rotundifolia.*

seed moistened with the last attenuation cures this terrible disease with this single dose without endangering the health of the child in the slightest degree.' "

According to Hahnemann the process of succussion and trituration develops in drugs, or imparts to drugs, more and more power the further the process is carried on; or the more dilute and attenuated they become by this process the more actual power and force is engendered; and this force, or power, started in the material, becomes greater as the material becomes less and less; and finally, when the material has passed away, the accumulated power is transmitted or passed over to the spiritual; and that goes on increasing in power *ad infinitum*, if the process is continued.

According to the process, Hahnemann believed that, when the spirit world was reached with drosera ("the fifteenth attenuation [spiritualization"]), provided each potency had received twenty succussions instead of two from a powerful arm, then it would endanger the life of a child with whooping-cough.

He directed that each successive dilution should be succussed twice, if more than that, the power would be developed too rapidly, for each and every additional shake meant more power. Hence, in the case of drosera, when the point is reached where there is no drug material left—where the body of the drug is all gone, then the spirit of the drug, like the soul of John Brown, goes marching on mighty in its power and deadly in its effects. Now, if this be so, it should be regarded, by the law of the State, malpractice to dispense the so-called high potencies without a label signifying that they are deadly; and it should be generally understood and taught that a high dilution should be brought low by dilution; but mind you don't shake it. *The only safety in diluting a high potency is in not succussing it.*

Such is the logic of Hahnemann. To-day it is nonsense! folly! delusion! craziness! and there is no danger of killing a child with drosera in any dilution. Hahnemann takes us out of the tangible into the spirit world—of which we know nothing; and the nearer we approach to nothingness, if on the given scale, by jerks, the nearer, he tells us, we approach to something—call it disembodied power, which is a misnomer, a fallacy.

The more material the more power. We cannot comprehend or utilize a force independent and separate from material. In all science, in all mechanics, there is no such thing as power without material. This is a self-evident truth, which confutes and confounds and makes a lie of Hahnemann's doctrine of potentiation.

A drug's usefulness, or beneficial influence, may be increased by dilution, but not its power. The less material the less power, on general principles, whether it is succussed or not. Does a tornado become more powerful by dilution? Does a man's arm become stronger by emaciation?

Is the thirtieth attenuation of prussic acid more powerful and deadly, when succussed according to Hahnemann's directions, than the pure acid itself?

Power or potency is one thing; but the fitness, the adaptability of things is something else. A drug, by dilution or trituration, may be better adapted to the cure of disease, it may, by that process, be the better fitted for efficient use by the system; but its power has not thereby been increased; and it does not continue to increase as the material is lessened *ad infinitum*.

There is no such thing as a high potency, because power does not increase with successive diminution of matter, notwithstanding it may have been triturated or succussed. You cannot get out of a drug anything more than is in it; and succussion and attenuation possess nothing and give nothing. There is no such thing as a high dilution, for the so-called high dilutions contain none of the original drug material. In order to dilute, there must be something for dilution—some material; and, if there is no material, there can be no dilution.

Force or power cannot be conveyed or exhibited beyond matter nor without matter; and to claim that it can, or to advance such doctrine, is nonsense; for it is unscientific, untenable, undemonstrable and false. I close with a little prayer—"With all thy getting, get understanding." Amen!

[All this is very interesting, and suggests the query: What is a homœopath?—Editor of REPORTER.]

Removal of the Uterine Appendages in Cases of Functional Neurosis.

At the meeting of the Obstetrical Society of London, January 7, 1891, Dr. Playfair read a paper on removal of the appendages of the uterus for neuroses, an abstract of

which appears in the *British Medical Journal*, January 17, 1891. He detailed several cases that had come under his observation: —1. A case of neurosis treated by removal of the appendages, without benefit, subsequently cured by systematic treatment. 2. A similiar case in which the operation was recommended, and about to be performed, when the patient refused her consent, likewise cured by systematic treatment. 3. A case of neurosis, in which there was distinct evidence of structural disease of the appendages. In this instance the neurotic symptoms were first dealt with, in the hope that the patient would be sufficiently bettered to avoid the necessity of operation.

The subject of hystero-epilepsy and mania treated by removal of the uterine appendages was considered, and an illustrative case given. The general conclusions arrived at were:—1. That the removal of the appendages is not a legitimate procedure in cases of purely functional neurosis. 2. That when marked structural disease of the appendages co-exist with severe neurotic conditions, the latter should be treated in the first instance, in the hope that operation might be avoided. 3. That in hystero-epilepsy and hystero-mania the results of operation have been so unsatisfactory that it is a procedure of very doubtful expediency, and not to be recommended.

Sir Spencer Wells referred to a pamphlet by Dr. Ross, of Toronto, on "The failure of the removal of the tubes and ovaries to relieve symptoms." Dr. Ross says: "To operate on organs not diseased for the relief of indefinable pain symptoms, hysterical symptoms, cataleptic symptoms, epileptic symptoms, is in my mind unjustifiable. A craze seems to have taken hold of the profession. The axiom seems to have become, if a woman has indefinite pains and local symptoms, take out her ovaries. This axiom requires a radical change." Dr. Ross went on to say: "I have seen these unjustifiable operations done both in Europe and America. . . . Many cases in which ovaries and tubes are removed to relieve certain nervous symptoms remain unrelieved. . . . Many cases I hear of as cures are not cures. . . . From our many failures to remove nervous diseases, as hysteria and epilepsy, by castration, we can see that the ovaries play but a part in their causation; and I believe that we might as well hope for relief of these diseases by enucleation of both eyes as by removal of both ovaries, or both tubes, or both tubes and ovaries, or even tubes, ovaries, and uterus." Dr. Ross related a case in which he removed the ovaries in 1886. In 1888 he was able to report that his patient had been in splendid health ever since operation, but in 1890 had to say: "her mental condition is not what it was before. She seems lazy, indolent and fat, and is not the bright little woman she was before the operation, even when she had her aches and pains. Sexual intercourse is only indulged in as a marital duty; it gives neither pain nor pleasure." Then Dr. Ross proceeded: "Many deaths from these operations have been recorded. . . . A girl's prospect of marriage, maternity, and a happy life are blasted forever by such a procedure." Dr. Ross then referred to a case in which a woman of his acquaintance was operated on in the provinces, and her case was brought before the Gynecological Society in December, 1888, very soon after the operation as a practical cure. Sir Spencer Wells had seen that lady that day; she had never been well since the operation, but very much worse than before, and her case instead of being a cure was a deplorable and disastrous failure. He had seen other cases almost as unsatisfactory, and he fully concurred in all that Dr. Playfair and Dr. Ross had said against unnecessary and unjustifiable mutilation for transitory disease.

Operation for Cerebral Hernia.

The *Western Medical Reporter*, January, 1891, contains an interesting report of a successful operation for cerebral hernia by Dr. J. Frank, of Chicago.

On August 11, 1890, the mother brought a little three-year-old girl to the Cook County Hospital, saying the child was kicked by a horse which was being shod. On examination paresis of the left arm and leg was found. The right pupil was somewhat larger than the left and both reacted to light. Stupor was well marked. After shaving the head, the scalp was found to be intact, with the exception of its being discolored. On account of swelling, a depression of the skull could not be determined. The stupor and paresis justified an exploratory operation. After the operation, there was an immediate improvement of the paresis and stupor. Several days after the operation the child was able to sit up in bed and play.

Where the dura was destroyed and over the region where the drainage was placed, a hernia developed, which kept on growing larger. As the hernia kept on increasing in size, an operation was decided on. The method adopted in this case is as follows: The scalp was dissected from the tumor where it was reflected and firmly united. The dissection was carried on until healthy brain tissue was reached, when, with the handle of the scalpel, the hernia was cut away, during which time cerebral fluid oozed out. As soon as the hernia was removed the brain filled out the empty space. A smart hemorrhage now succeeded, which had to be controlled by packing. It was seen that the dura could not be brought together, so the edges of the scalp were freshened and united with interrupted sutures. A compress was put over the wound to keep the parts as quiet as possible and for the purpose of securing primary union, as upon this rested the success of the operation. The evening of the following day the child had a slight general convulsion, commencing in left arm and leg, followed by stupor which lasted about six hours, which apparently was produced by the compress being strapped on too tightly over the area where the brain pulsated against the scalp.

Four days after the operation the child was running about the yard. In a week the stitches were removed. Everything looked favorable until about the second week after the operation, when a small point in the middle of the line of the incision commenced to slough. Fortunately, the sloughing did not extend very far, leaving the parts in a fair condition.

Practice by Syphilized Practitioners.

The *Medical Press* January 21, 1890, says: A foreign contemporary discusses the question of the duty of a medical man who has been unfortunate enough to contract syphilis in the matter of continuing to practice his profession. Everything must, of course, depend upon the nature of the manifestations, their site and their age. It is obvious that no conscientious man with a specific ulceration on the hand would undertake any obstetrical or surgical operation involving the risk of infection to the patient. There is no reason to suppose that infection is possible in the absence of cutaneous lesions, though any serous of sanguineous exudation might conceivably convey the contagion. This, however, is still a moot question, and the circumstances under which a medical man would be constrained to cease to practice are rare and improbable.

Therapeutic Use of Monesia Bark.

The so-called "monesia bark" (*Cortex monesiæ*, or *cortex Buranham* or *Guaranham*) is derived chiefly from a Brazilian tree *Chrysophyllum glycyphlœum Casaretti*, but also from other six varieties of the species *Chrysophyllum*, belonging to the natural family *Sapotaceæ*. According to Henry and Payen, the bark contains saponin, an allied body "monesin," tannic acid, glycyrrhizin, wax, a crystalline fatty substance, etc. Years ago the drug (in the shape of a solid aqueous extract, termed simply "monesia") was much vaunted and used, especially in France, as a tonic and an astringent. Subsequently, however, it gradually fell into oblivion. Quite recently, Dr. Pavel G. Rozanoff, of Moscow, has once more drawn the attention of the profession to the long-forgotten remedy (*Moscow Inaugural Dissertation*, 1890), emphatically pointing out that monesia actually affords an excellent expectorant and astringent agent. He describes a number of cases of respiratory and intestinal affections (acute and chronic bronchitis, pneumonia, subacute enteritis, chronic diarrhœas, etc.), in which he most successfully resorted to the internal administration of a mixture, made of from ½ to 1 drachm of aqueous extract of the bark to 6 ounces of water. The mixture was always given in tablespoonful doses, repeated every two hours. The author's experience seems to justify the following general propositions. 1. The bark affords a good expectorant, which is dependent upon its containing saponin and monesia. 2. At the same time, owing to a rich proportion of tannin, the remedy constitutes a good astringent. 3. It is quite free from any unpleasant accessory effects and hence, as an expectorant, should be preferred to ipecacuanha, senega and such like drugs. It is especially indicated in cases of respiratory disease in which a more or less prolonged administration of an expectorant is deemed necessary, as well as in cases where the ordinary expectorants are apt to give rise to gastro-intestinal disturbances. 4. As an astringent monesia

proves to be useful in chronic diarrhœas. 5. In virtue of its simultaneously possessing expectorant and astringent properties, the bark will be found eminently beneficial and convenient in cases of co-existing chronic catarrhal affections of the respiratory and intestinal tracts.

Medical Practice in Missouri.

The *St. Louis Courier of Medicine*, January, 1891, says:

"Unless steps are taken in the near future to raise the standard of requirements for the practice of medicine and surgery in this State, we will find to our sorrow and dismay, that when the higher standard adopted by all our sister States goes into effect, Missouri will be overrun with 'quacks.' We have an abundant supply of them now, without any emigration of the 'scum and rot' of other States. The very day they are affected by this change in the present laws, there will be an exodus, the like of which was never seen. The wagon-roads from every point of the compass will be crowded with the vehicles of the traveling quack with their banners flying, hurrying to the Mecca; the paradise, which the narrow-minded policy of our State government has maintained for years." To this, it adds: "Let us arise in our might ere our strength and present power has passed away, and place Missouri on an equality with all the States around us!"

Caustic Treatment of Carbuncle and Diphtheria.

Dr. Gëorgy Ï. Gisler, of Semipalatinsk, describes (*Proceedings of the Omsk* [*Siberian*] *Medical Society*, No. 8, 1890, p. 187) six successive cases of severe carbuncle of the neck, rapidly cured by the application of the following mixture, prepared *extempore*.

℞ Potassæ s sodæ causticæ fusæ
Magne·iæ ustæ ää . . . . . gr. ii
Aquæ destillatæ . . . . q. s. ut ft. linimentum

Sig. Carefully paint over the diseased area, by means of a brush, until an equal layer, one-fourth inch thick, has formed. Then cover the part with a piece of linen, soaked in a 50 per cent. solution of carbolic acid, or in wintergreen oil.

Simultaneously, antefebrin (5 grains at bed-time) and quinine (from 10 to 15 grains similarly at bed-time) were given internally. In every one of the cases, in 3 or 4 hours after the application a profuse perspiration appeared and the temperature returned to the standard. On the next day the ulcer was found to be replaced by a black, dry and firm scurf, which gradually became detached from the subjacent tissues, leaving a soundly granulating and rapidly healing surface.

Dr. Gisler states, further, that in such cases of gangrenous faucial diphtheria as are not accompanied by an intense enlargement of the submaxillary lymphatic glands, he invariably obtains most satisfactory results from cauterizing the diseased region with chloride of zinc. He commences the treatment with carefully touching the area with the solid chloride; two hours later he paints the region with a 50 per cent. solution of the salt, and subsequently passes to an 8 per cent. one, repeating the application every two hours. After each *séance* the patient is given internally a solution of bicarbonate of soda ("to decompose the zinc salt, if swallowed"). If the nasal passages are simultaneously involved, he irrigates them with a solution of perchloride of iron in a saturated chlorine water and lets the patient gargle his throat with the same fluid. Of internal remedies he administers calomel "in drastic doses," in the beginning of the treatment, and subsequently gives salicylic acid every two hours (in 5-grain doses to a child under 2 years of age, and from 15 to 20 grains to older patients). The patient should be constantly kept in the room at 8° or 10° Reaumur (50°–54.5° Fahr.) [This would be thought a low temperature in this country, for a sick room.—Ed. Reporter.]

Fish Poison.

The *Vierterjahrsschrift für Gerichtliche Medicin*, January, 1891, calls attention to a very important matter in connection with the use of fish as a food. It appears that an investigation of the result of eating fish preserved on ice for use in the London markets, has led to the discovery that those were most dangerous which were kept in immediate contact with the ice. Poisoning by fish which had not been in contact with ice was not observed at all. This is attributed to the influence of the water derived from the ice, and bearing whatever impurities it had had before being frozen, which promotes the formation of the animal alkaloids known as fish poison.

THE

MEDICAL AND SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

GYNECOLOGICAL SUGGESTIONS.

With characteristic felicity of expression, Professor Goodell has chosen for the title of a recently published paper the expression "What I have Learned to Unlearn in Gynecology."

In this paper, while he confines himself to the discussion of misconceptions which pertain exclusively to maladies peculiar to women, he adopts a course, which, if followed out by others entitled to speak authoritatively, would prove of incalculable value to the profession.

The history of recent medicine records the uprooting of time-honored dogmas to an extent heretofore unexampled; and the experience of Dr. Goodell, which he so frankly relates, must have been that of all progressive men. If they would record, in short, concise papers, what they have found to be wholly unreliable, it would deter many from undertaking what is not only of no value, but what unfortunately is too often positively injurious, and, in addition, it would act as an incentive to more careful investigation into the causes which underlie disease, and the adoption of better means for its relief.

The paper which suggests this article deserves thoughtful consideration for the sound views gathered from a wide and varied experience. The first subject considered is the disposition, prevalent both in the profession and among the laity, to regard the menapause as responsible for a large percentage of the maladies of matronhood, and, having accepted that view, to allow without investigation conditions which can be relieved only by early interference, to advance so far that, when recognized, the sufferer is beyond relief, either by reason of the fatal nature of the disease itself or the ravages which it has produced in the vital energies. Dr. Goodell very strongly insists that the climacteric should not be considered a cause for uterine disease, and suggests that unusual hemorrhages or other discharges occurring at this period in a woman's life should always be regarded as symptomatic of the existence of organic disease, calling for careful investigation and prompt treatment. He points out that cancer of the cervix, polypi or fungus vegetations of the endometrium are almost invariably responsible for these conditions, while the part played by the menapause in the disorders attendant on the climacteric is almost exclusively detected in the many nervous phenomena present at that time, or as a factor in the production of insanity.

The belief that the menstrual period is unsuited to surgical procedure he clearly shows to be a fallacy, pointing out that, where the curette is to be used for the removal of uterine vegetations, this time is the best, because they are then swollen by the afflux of blood and can be more readily removed. He says, "there is no surer way of checking a menorrhagia or of stopping a

metrorrhagia than by curetting the womb during the very flow." Indeed, where time is precious, the gravest operations not only may be, but, with few exceptions, should be performed. Further he says, "while I do not select this period for the removal of ovarian cysts or for other abdominal work, such as the extirpation of the ovaries, of a kidney, of breaking up intestinal adhesions, etc., yet I have not hesitated to perform these operations at such a time, and have never had reason to regret the course. The only operations that I should dislike to perform during menstruation would be those involving the womb itself—such as the removal of a uterine fibroid or a partial or a complete hysterectomy, and the various operations for uterine cancer, etc. . . . . For obvious mechanical reasons it would also hardly be wise to sew up the torn cervix of a menstruating womb."

Dr. Goodell's suggestions in regard to the management of lying-in women, a subject of the greatest importance and one which confronts so many of us, is so practical that we cannot refrain from reproducing it in full. "In the lying-in chamber," he says, "the fear of septicæmia will ever haunt me, but I have long since abandoned the idea cherished by that class of waistless and witless nurses, now happily obsolescent, that the parturient woman is to be swathed like a mummy and kept as immovable. What earthly harm can accrue to a woman after a natural labor if she turns over from side to side, sits up in bed, or even gets up to use the commode, if she feels like it, I cannot see. Natural labor is a physiological process, not a pathological one, but tradition has thrown around the lying-in bed a glamour of mischievous sentiment.

"In relation to this, let me express my disbelief that mammary abscess comes from 'caked' breasts, or from breasts over-distended from a secretion too great for the infant's needs. Mammary abscess in the suckling woman comes, in my opinion, from cracked nipples, and from cracked nipples alone. In proof of this let me ask my readers if any one of them has ever had a case of mastitis after a miscarriage, or one of gathered breast following a still-birth—always provided the breasts were let pretty much alone so far as pumping and sucking are concerned. Under these circumstances the unsucked and unpumped breast will swell up and grow painfully hard, but will not inflame or suppurate. Let me not be understood as saying that an over-distended breast should not be relieved by sucking or pumping; but the means employed for this relief must be so sparingly used, and at such long intervals, as not to crack the nipples. This immunity from mammary abscess after miscarriages and still-births is attributed by the physician to his local applications of belladonna, or other milk-drying drugs. But it comes from the absence of the exciting cause of cracked nipples—a sucking child."

We call attention to these suggestions of Dr. Goodell because they are eminently worthy of careful consideration by all who have women for their patients, and because they illustrate a spirit in the art of medicine which it is pleasant to applaud and to commend for imitation.

NATURE OF LUPUS.

Within the past few months, since the announcement by Dr. Koch of the discovery of a remedy for tuberculosis, English-speaking people have been made familiar with the name lupus. In reply to their inquiries as to what lupus is, it is not too much to say that the almost invariable answer has been, it is tuberculosis of the skin. The teaching of German and American dermatologists is practically unanimous on this point, and the treatment of lupus with Koch's remedy assumes it as a starting point. It is with much interest, therefore, that we have read the first of Mr. Jonathan Hutchinson's Post-Graduate Lectures on the "Nature of Lupus," in the *Lancet*, Jan. 17, 1891.

This author says that the sum of the evidence seems to him much in favor of the belief that lupus is a specialized form of chronic inflammation rather than the result of infection. He does not altogether, in his theory, exclude the influence of the parasite, but appears to think that conditions of local irritation favor the implantation of the bacillus, as ploughing and manuring of a field prepare it for the sowing of seed. He declares, what every one knows to be true, that it is extremely difficult in many cases to diagnosticate lupus from scrofulous ulcers and ulcerating chilblains. But whenever a chronic inflammation of skin or mucous membrane, not due to syphilis, shows a persisting tendency to spread at its edges, to produce satellites near it, and to leave a condition of scar behind it, such a process Mr. Hutchinson regards as lupus. Another condition, which he believes to be diagnostic of lupus, is the presence beneath a thinned layer of epidermis of a deposit or growth of a semi-translucent ("apple-jelly") granulation material, often in considerable thickness.

As to the classification of lupus, Mr. Hutchinson questions whether clinical evidence can be held to prove the alliance of lupus with tuberculosis, rather than with cancer. As an argument against the bacillary nature of the disease, he remarks: "I doubt much if many observers could collect from their own observations as many as four cases of lupus in which the patients has subsequently succumbed to any form of internal tuberculosis." The *Lancet*, however, reminds him editorially that Besnier has observed phthisis in association with lupus eight times in thirty-eight cases of lupus, that is, in over twenty per cent. of the cases.

Lupus is so rare in this country that we must look to the pathologists of Europe to settle the question of its nature. Taking the skin dispensaries in connection with the hospitals of Philadelphia, we doubt if they average one case of lupus vulgaris a year.

Mr. Hutchinson's communication is remarkable as showing that a man of great experience and close observation is far from believing that lupus is tuberculosis, in spite of the fact that scarcely any other voice is heard against that view. If Koch's remedy were to prove of unfailing accuracy in the detection of lupus, it would be a valuable agent; but it has not attained this position yet, so that we must look to older means of diagnosis for help.

In order to estimate fairly Mr. Hutchinson's paper, it should be borne in mind that he does not accept all the pathological views which now prevail; and, on the other hand, that tubercle bacilli, which are generally accepted as an evidence of the existence of tubercular tissue, do not seem to be found in the very early stages of lupus.

HOMŒOPATHS AND THE MEDICAL EXAMINERS' BILL.

In order that the readers of the MEDICAL AND SURGICAL REPORTER may understand into what a fever of excitement the homœopaths in Pennsylvania have been thrown by the proposition to have their graduates examined by some body besides their own College Faculty, we reproduce in another part of this number of the REPORTER an editorial from the *Hahnemannian Monthly*.

We take it for granted the readers of the REPORTER and the community will appreciate the signifiance of the fear which seems to fill the homœopathic (college?) breast when there is any chance that the State may take into its own hands the determination of fitness for practicing medicine, as contrasted with the composure with which the Regular School consents to undergo—without making any conditions—any test of merit which the wisdom and honesty of our law-givers may appoint.

This singular contrast receives a curious side-light in view of a letter published in the REPORTER August 24, 1889, to which so far we have seen no answer. This letter is re-

printed in the present issue, so that it may be considered in connection with the opposition to a Medical Examiners' bill which would make it impossible for a graduate of the Eastern Penitentiary to get a medical education, a diploma, and endorsement by the Hahnemann Medical College, and the legal right to practice medicine, in the short space of eight months!

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

ILLUSTRATED ENCYCLOPÆDIC DICTIONARY. By Frank P. Foster, M. D. Volume II. 4to, Cac.—Fasay, pp. 753-1544. New York: D. Appleton & Co., 1890.

This is the second volume of the Dictionary of Medicine edited by Dr. Frank P. Foster, of which we noticed the first volume October 6, 1888. The second volume is fully up to the standard of the first in completeness and reliability. For a medical dictionary there is some inequality of space to different subjects. For example, the word "corolla" occupies more than one page of space, and is illustrated with great completeness, while the word "douche" occupies as much space, and is illustrated with a variety of cuts which look as if they had been borrowed from the instrument makers. The principal advantage of the book, so far as we can judge, is the fact that it contains a very large number of words, and is that much superior to most medical dictionaries. It must have demanded an enormous expenditure of labor for Dr. Foster to carry on the work of getting out a volume like this in addition to his work as Editor of the *New York Medical Journal*, and we congratulate him upon the high degree of excellence to which he has brought it.

CHARLES LETTS & CO.'S A B C MEDICAL DIARY AND VISITING LIST. London: Burroughs, Welcome & Co., 1891.

We have received a copy of this English book, which corresponds with our American Visiting Lists. Nearly one-half of its thickness is made up of reading matter of interest and value, while the tabular parts are very well ruled and conveniently arranged. The whole is well made, as a book, and neatly bound, though we miss the cover flap which is put upon all similar books in this country.

Literary Notes.

—The *Dietetic Gazette*, with the number for January, 1891, passed into the editorial management of Dr. Simon Baruch, of New York. Nothwithstanding the principles announced in his salutatory, the Department of "Annotations" (presumably editorial) contains no less than thirteen reading notices.

Notes and Comments.

Endorsing Diplomas in Pennsylvania.

In the Medical and Surgical Reporter, August 24, 1889, was published a letter from one of our subscribers who said: In your issue of August 3, there appears a communication from "Jno. E. James, M. D., Registrar of Hahnemann Med. College of Philadelphia," in which he takes you to task for not basing an Editorial in the Reporter, July 13, 1889, upon facts nearer home than England. Now I wish to relate some facts, and would like to have made manifest the consistency between them and the declarations in the article referred to above.

On the 22d day of April, 1884, Hiram T. Kinsman registered in the Prothonotary's office in Bradford Co., Pa., as a practitioner of medicine, claiming that he had been in continuous practice in this county since 1871—"Degrees, 'None'"—enumerating five different places in the county where he had been in practice during that time. Subsequent events, however, showed that there was one place more of alleged practice (not in the county) that he did not have recorded on the Register.

The said Kinsman was charged with illegal registration. During the trial it was in evidence, and admitted by defendant, that for four years of the time of his alleged practice in Bradford Co. he was an inmate of the Eastern Penitentiary. His crime was criminal abortion. It is said that the woman died of hemorrhage, which he did not know how to control. Kinsman claimed that he practiced while in prison, by sending prescriptions to persons in this county. Suffice it to say that the jury disagreed; but before the second trial, Kinsman agreed to have his name stricken off the Register, and this was done by order of the court on September 6, 1886. Kinsman was absent a few months from home (at least it was so reported), and on May 9, 1887, registered again—this time as a graduate of "Bennett *Eclectic* Medical College," "endorsed by *Hahnemann Medical College of Philadelphia*, and Eclectic Medical College of City of New York."

Here is an ignorant migrating "doctor," convicted of a penal offense, and of false registration, who, after not more than a few months of medical study, is registered as endorsed by the college that "Jno. E. James,

M. D.," says sits on such a high and lofty elevation and requires a high standard of medical knowledge! I would say, with Jno. E. James, M. D., "Please note . . . . the whole of numbers 4 and 5." Yes, sir, we have noted them, and desire to ask what kind of *professional and moral standing* the person in question has, and what was the character and quality of his *examination* by the faculty of the Hahnemann Med. College?

Reading these rules in the light of these facts they appear very much like first-of-January resolutions. I think these rules need bracing up in the year 1889, without waiting until 1890 and 1891, judging by the case cited.

The Homœopaths and the Medical Examiners' Bill.

Under the amusing title, "The Proposed Allopathic Bill to Establish in Pennsylvania a State Board of Medical Examiners," the *Hahnemannian Monthly*, in its February issue, publishes the following editorial.

This act provides for the appointment, by the governor, of a board of examiners consisting of nine members, three of whom shall serve for one year, three for two years, and three for three years, in the first instance, and thereafter annually the governor shall appoint three members to serve for three years. The members of the board shall be graduates of a legally chartered college or university having power to confer degrees in medicine. They must also be citizens of the United States and of Pennsylvania, and shall have been in active practice for a period not less than ten years. Not more than one shall be appointed from the same county, and none shall be a member of the faculty or staff of any medical school or university. The applicants shall be examined in anatomy, physiology, chemistry, toxicology, pathology, hygiene, materia medica and therapeutics, principles of medicine, surgery and obstetrics. Any candidate for examination may choose the system of materia medica and therapeutics in which he or she shall be examined, and no one shall be rejected on account of adherence to any school of practice. The board shall hold two meetings in each year —one at Philadelphia and one at Pittsburgh. The Pittsburgh *Medical Review*, in commenting upon this bill, the birth of the committee of the presidents of the various allopathic county medical societies, says: "The proposed bill is, of necessity, not such an one as the regular members of the medical profession would desire, and what strict adherence to all that is best, from a *humanitarian* standpoint, would demand, for, in that case, it would confine the appointing power of the governor to the ranks of the *regular scientific practitioners*," . . . etc. "It would seem only just, however, that the representation on the examining board should be governed by the percentage that the members of the sectarian schools bear to each other." The members of the homœopathic school know very well that this bill is "not such an one" as the trades-union spirit of the self-styled "*regular scientific practitioners*" demand. Of course, its apparently liberal provisions are framed through dire necessity. Of course, the membership of the board would have been composed *exclusively* from their own selfish sect, if they had entertained a grain of hope that it could have been forced through the legislature in that shape. Of this no one entertains the slightest doubt. Liberal as these provisions may appear through allopathic spectacles, they will not do. Homœopaths have not forgotten how the members of the allopathic committee betrayed the trust reposed in them in 1889; consequently, the members of the homœopathic profession have no confidence in the honesty of purpose of the allopaths. We object to this bill, principally because it does not definitely fix the composition of the board. We must have an equal representation. The editors of the *Review* are in error when they think "that it is only just that the representation on the examining board should be governed by the percentage of members of the different schools of medicine." This question is not one of relative members of the various schools; the proposed bill will not affect any physician now in practice. It is designed to examine into the fitness to practice of future applicants. Each school should have the right of absolute control over the members of its own faith. The schools of medicine stand before the State as units, and as such should have equal representation. The homœopathic school will have nothing less. The allopathic physicians who framed this bill are indulging in a bluff; they are hugging the fond hope that they will receive the majority of the appointments, and this risk we will not take. How can we take it, in the

face of their open boast, that once they can obtain an exclusive examining board they will stamp out of existence their hated rivals?

It is the height of folly to place the power of licensing of homœopathic physicians in the hands of a school that libels us by charging us with ignorance; and then openly proclaims that it will not aid us to knowledge. This is shown by the recent act of the New York Polyclinic in refusing to accept homœopathic physicians as students, and the University of Vermont in refusing to acknowledge a homœopathic diploma as evidence of attendance on medical lectures. We do not need the aid of either of the above-mentioned institutions; but we mention these facts in order to show the animus with which our enemies are actuated.

Lupus—or Tuberculosis of the Skin.

In a recent lecture, published in the *Medical Press*, January 28, 1891, Mr. Jonathan Hutchinson discusses the question: Whether or not lupus vulgaris is a form of tuberculosis, and how far clinical evidence supports the hypothesis that lupus vulgaris is of bacillary origin?

In reference to this he says: Lupus vulgaris is not a disease which attacks infants or young children. In exceptional cases it may occur even to the youngest, but commonly it waits until childhood is well advanced, or even until the period of puberty is passed. It is said by some never to begin in old age, but this is a mistake. We often see it begin at or after middle life, and in a few instances its subjects are advanced in years. When the latter is the case, it displays somewhat peculiar features, and may probably be ranked with that group of maladies to which Sir James Paget has given the name "senile scrofula." Although in many cases it is multiple in its manifestations in the skin, several, or perhaps very many, patches being produced, there is, with the fewest possible exceptions, no tendency to infect other parts. The lymphatic glands do not suffer, nor do the lungs, the bones, the joints, or the intestines ever become affected. Nothing is less common than to see a lupus patient pass into phthisis. Thus we may believe that the infective material, be it what it may, is one which finds a suitable home only in cutaneous or mucous structures. If it be a bacillus, it is a selective one, and it keeps to the tissue in which it had its first development.

The most typical forms of common lupus are often coincident with good health on the part of the patient, and the absence of any family history of tendency to tuberculosis. Of course, there are many exceptions to these statements, but all observers agree that they express the general truth. If, indeed, it were asked whether the clinical evidence more favored the belief of the alliance of lupus with tuberculosis or with cancer, I am inclined to think that the reply would have to express hesitation. Tuberculosis and the cancerous process have hitherto been held to observe towards each other something of a position of antagonism. Those who are liable to the one are not prone to the other, and the two are but very rarely found together. Almost all who have written on lupus have, however, been struck by the fact that parts affected by it not very infrequently take on cancerous growth. The evidence on this point has recently been collected by Bayha, of Tubingen, who from his own experience has collected no fewer than four cases. I doubt much if many observers could collect from their own observations as many as four cases of lupus in which the patients had subsequently succumbed to any form of internal tuberculosis.

In making these remarks I am far from wishing to ignore either the general impressions or the collected facts which favor the belief that there is some bond of connection between tubercular affections and lupus. What I contend for is that it is far less close than is generally believed. The impressions which most of us have, I expect, formed on this subject go far ahead of any proof of a statistical kind which we could supply. If I may be permitted to anticipate a little what I shall have to say in my next lecture, I may here mention the unexpected fact that statistical results are different in respect to lupus erythematosus. In this latter no observer has, I believe, succeeded in detecting the bacillus, yet it is far more frequently in close association with tuberculous conditions than is lupus vulgaris. Some light may perhaps be obtained for the elucidation of this difficult question by observation of the very earliest stages of lupus. We are so accustomed to see this chronic malady after it has been long existent, and when its peculiarities are well declared, that very little has been done in the attempt to describe, still

less to depict, its initial conditions. I much suspect that if we knew them we should have to acknowledge that they are often such as cannot be recognized as lupus at all. The disease may, and often does, originate in a condition of chronic or recurrent congestion and swelling not in the first instance to be distinguished from a chilblain. Or it may start from what looked like tuberous acne at the end of the nose, or from patches in the middle of the cheek, which had been often congested in the act of blushing or in the flush which attends indigestion. Slight injuries, insect stings, bruises, burns, etc., may become its starting point. In almost all cases something not distinguishable from a chronic papular inflammation is, I believe, the earliest local condition which is observed. The apple jelly may form before the disease is far advanced, but it is never present at the very first. Nor do we ever see anything in the least resembling a tuberculous ulcer. The early stage is in many cases insidious and prolonged, but it is not so in all. In some a tendency to rather rapid infective spreading is early manifested, and while it is so the conditions produced resemble rather those of common inflammation than anything which could be recognized as specifically lupus.

In concluding, Mr. Hutchinson says: I have here endeavored to bring in review the principal facts which, from the clinical standpoint, appear likely to help us to answer the question whether lupus vulgaris should be regarded as tuberculosis of the skin. We have seen that there is no evidence that it ever begins from the implantation of tuberculous matter, that it is only exceptionally associated with tubercle in the viscera, and that it never causes infective gland disease. We have also seen that there are other affections of the skin which do not resemble it, which are much more closely associated with tubercle and with scrofula. We have seen also that its remarkable preference for certain regions and parts seems to imply that the influence of cold is by far the most common of its exciting causes. I may own that the sum of the evidence seems to me much in favor of the belief that lupus is a specialized form of chronic inflammation rather than the result of infection. In suggesting this I am well aware that it is merely a negative conclusion which is liable to be overthrown at any time by the accumulation of positive evidence. It may be that in the future the presence of bacilli in lupus-products may be demonstrated in earlier stages, and much more constantly than has yet been the case. The results of Koch's injection treatment may possibly force us to believe that there is something about lupus which connects it far more closely with tuberculosis than I have admitted. I prefer for the present to say nothing about the results of the treatment already obtained.

Association of American Anatomists.

The third annual meeting was held Dec. 29 and 30, 1890, in the anatomical lecture-room of the Harvard Medical School, Boston, Mass. It was presided over by Dr. F. D. Weisse, Second Vice-President, and Dr. Thomas Dwight acted as Secretary *pro tem.* Papers were read as follows: *Corrosion Preparations*, by Dr. S. J. Mixter; *Studies on the Spine*, by Dr. Dwight; *A Comparison of the Fibrin Filaments of Blood-lymph in Mammalia and Amphibia*, by Prof. S. H. Gage; *The Semi-lunar Bone*, by Prof. Shepherd; *The Structure of Protoplasm and Mitosis*, by Dr. Carl Heitzmann; *The Homology of the Cerebro-spinal Arachnoïd with the other Serous Membranes*, by Prof. F. W. Langdon; *The Occlusion of the Rhinocœle (Olfactory Ventricle) in the Dog*, by Mr. P. A. Fish and by Prof. B. G. Wilder; *The Relations of the Olfactory to the Cerebral Portion of the Brain; The Brains of a Cat and of a Sheep lacking the Callosum; Owen's Nomenclature of the Brain, with suggestions based thereon.*

With one exception the papers were illustrated by specimens, photographs or diagrams, and all were fully discussed.

The Committee on Anatomical Nomenclature (Professors Leidy, Harrison Allen, Frank Baker, Thomas Dwight, T. B. Stowell and B. G. Wilder) was authorized to publish, as its second report, "such general and specific recommendations as may be unanimously agreed upon by them."

The following were elected members: Dr. W. L. Dana, of Portland, Me.; Dr. John C. Munro, of Boston, Mass.; Mr. Pierre A. Fish, of Ithaca, N. Y.

The next meeting will be held at Washington, D. C., September, 1891, at or about the time of meeting of the Congress of American Physicians and Surgeons. The officers for that meeting are as follows: President, Joseph Leidy; Vice-Presidents, Frank Baker, F. D. Weisse; Secretary and

Treasurer, D. S. Lamb; Executive Committee, Harrison Allen, Thomas Dwight and B. G. Wilder.

Dangerous Lunatic.

The commission appointed to investigate the mental condition of James M. Dougherty, the escaped lunatic who returned and killed Dr. George F. Lloyd at the Flatbush Insane Asylum last autumn, and who was tried and convicted of murder in the second degree in Brooklyn, has just reported.

The commission finds that Dougherty is suffering from monomania, and the malady is marked by hallucinations in the different senses and by delusions or false beliefs; delusions of commingled persecution and expansiveness, the patient imagining he has enemies who conspire against him, or that he is a man of unusual talent, beauty or importance. These delusions are always of great seeming logicality, and as the memory and reasoning powers are not affected, while the usual manner and behavior are altered, the patient seems sane enough to those who suppose that every lunatic is violent, confused or incoherent.

The commission finds that Dougherty comprehends the nature and purport of his trial and was capable of defending himself. The prisoner presents a case of great medico-legal importance. Dougherty's delusions caused him to believe that he was the object of a conspiracy, and a man of such surpassing personal beauty as to have been regarded, at one time, the handsomest man in the world, and his hallucinations that he saw Mary Anderson in various places where the evidence showed she had not been, led him to the formation of a murderous plan, inaugurated by the murder of Dr. Lloyd, which he acknowledges was wrong in a legal sense, and which was to have been continued by killing many others. He firmly believed that his commitment into the asylum was a great wrong, for which there was no legal redress, and determined to call public attention to it by violent measures notwithstanding that he expected to be shot in the attempt or killed by electricity afterwards.

These hallucinations in nowise interfered with his understanding the motive and purport of his trial, or prevented him from defending himself. He thoroughly understood the legal meaning of his trial; knew his rights far better than the average citizen; knew the legal punishment for his deed; deliberated as to whether he would prefer death or imprisonment for life or commitment to a lunatic asylum, and in all respects comprehended the trial with as keen intelligence as though he had been perfectly sane.

The commission and commissioners have been unable to perceive that his delusions and hallucinations marred in the slightest degree an unusually intelligent understanding of the trial, although it is not within its province to offer an opinion on his comprehension of his act in killing Dr. Lloyd. He is as dangerous a lunatic as it has ever been the lot of the committee to encounter.

Dougherty will be sent to an insane asylum for insane criminals.

Medical Legislation in Arkansas.

The *Journal of the State Medical Society of Arkansas*, January, 1891, says, editorially, that it is taken for granted that when the present act to regulate the practice of medicine and surgery in this State was passed by a former Legislature, and became a law, it was intended and expected that it would effectually accomplish the purposes for which it was put upon the statute books. It is also believed that if, through certain palpable defects the law is ineffectual and fails in its purposes, the present General Assemby will be fair and just enough to remedy its defects by amendment of the present, or the enactment of a new law, *provided* it can be demonstrated to the satisfaction of the members of the Legislature that the present one is fatally imperfect.

It then quotes from an earlier editorial, saying: "The iniquities of the medical practice act in this State have been so often discussed, and are so well understood that it may be deemed almost superfluous to say anything further on the subject; but what is here written is suggested with the idea that it may be well at this time to formulate into more definite shape its defects, that they may be the more successfully urged in favor of amendment of the present, or the enactment of a new law. First. The qualifications and mode of selecting the members of the county boards of examiners are objectionable on the ground that in the first place the appointing power is vested in men who, as a rule, are wholly incompetent to pass on the qualifications that ought to be possessed by professional gentlemen designated as

'learned in the sciences of medicine and surgery, of good moral character,' etc. Second. No definite standard of qualification is prescribed, such as that members of the boards shall be graduates of reputable schools or members of some medical organization, admission to which carries with it the proof that the antecedents of its members and their professional and moral standing have been investigated. Third. While the spirit of the law indicates that applicants rejected by one county board shall not be licensed by another than the State Board, the Attorney-General gave it as his opinion that the letter of the law did not prohibit rejected applicants from going from county to county until a board might be found that would grant them license. It is too well known that men most ignorant and wholly incompetent have been rejected by several competent boards, but still went from county to county until a board was found the members of which, being on a level with the applicants, have licensed them and they are to-day plying their vocation at the expense and to the detriment of innocent parties who are not competent to judge of the proper attainments that ought to be possessed by persons pretending to practice medicine and surgery.

"To cure these defects in the law, it is suggested, *First*, to have one State Board of Health, which shall have exclusive power to grant license. *Second*, to have a board in each congressional district and a State Board of Appeals. *Third*, to amend the present law so as to require the members of county Boards to be graduates of medicine in good standing and to prevent a rejected applicant from applying for license to any other board in the State than the State Board. The idea adopted at the last meeting of the State Medical Society was the one recommended by the Committee on Medical Legislation, viz.: 'The appointment of one board known as a State Board, and the repeal of all existing laws on the same subject.' This is undoubtedly the simplest and best, but whether it could be accomplished against the opposition of members of the existing county boards, is questionable. At any rate the Committee of the State Society on Medical Legislation ought to commence to ask for the very best, and then if that cannot be obtained, substitute the next best, and so on until one of the proposed remedies shall be accepted by the Legislature and a law enacted accordingly."

Dirtiest City in the World.

Harper's Weekly says that the citizens of New York are not bashful nor backward in celebrating the greatness of the city, and in claiming for it a metropolitan primacy. They naturally believe that it is the centre and head of America, and cannot but suspect that foreigners from the effete despotisms must greatly exult when at last, after ages of oppression and suffering, they arrive in the bay dominated by Liberty Enlightening the World, step ashore at the Battery, and tread the Broadway of what must seem to them a kind of New Jerusalem.

It will not deny also that some foreign places have a certain historic and romantic, literary and artistic, interest, for which New York, busy with more important affairs, has not yet had time. But it will attend to them presently and outdo the world. Such is the cheerful complacency of this good city. Yet it is droll and undeniable that with all its grandeur and kindly condescension to other famous towns it cannot keep itself clean. Greece and Rome and Germany and France and England may strive in vain to overcome it in renown, but garbage and refuse and litter and dirt of every kind and degree utterly subdue it. It may spend millions and millions of dollars for what it calls its government, and savagely resent legislative interference, and maintain thousands of stipendiaries of every grade, and denounce Dirt in public meetings, and thunder at it in a free and forcible press, and swear at it in clubs, and scold at it in private parlors, but Dirt remains triumphant, and, proud of its supremacy, compels New York to be known as the dirtiest city in the world.

How the Homœopaths Look at it.

Many readers of the REPORTER will doubtless be interested to see the following extract from the *Hahnemannian Monthly* (*News and Advertiser*), February, 1891, which just now is making common cause with the Eclectics against a Medical Examiners' Bill in Pennsylvania and breathing out "threatenings and slaughter" against what it calls the "allopaths." The question, Why are we Homœopaths? this journal says was answered by Dr. Wells Lefevr (*sic*) in a paper, read before the Southern Homœopathic Medical Association. He presented the following conclusions:

Because Homœopathy has the only known law for the prescription of medicine. Its death-rate is the lowest, as is shown in the following comparative statistics of Homœopathic and Allopathic treatments, covering a period of five years. (Compiled by Dr. Jos. Buchner.)

Homœopathic Death-rate, per 100 cases treated: Erysipelas, 0.8; diarrhœa, 0.9; fevers, 1.2; typhus, 13.3; pleurisy, 1.3; inflam. of bowels, 6.1; typhoid fever, 8.8; scarlet fever, 2.9; dysentery, 7.1; heart affections, 15.5; apoplexy, 28.5; consumption, 38.6; yellow fever, 6.6; pneumonia, 5.2; duration of illness, 11.75 days.

Allopathic Death-rate, per 100 cases treated: Erysipelas, 23.0; diarrhœa, 21.2; fevers, 5.3; typhus, 16.0; pleurisy, 15.6; inflam. of bowels, 41.0; typhoid fever, 14.9; scarlet fever, 20.75; dysentery, 26.8; heart affections, 51.7; apoplexy, 48.3; consumption, 48.5; yellow fever, 23.5; pneumonia, 20.4; duration of illness, 28.9 days.

Homœopathy is chiefly employed among the well informed and cultured people. Homœopaths can procure lower rates of insurance, on account of the lower rate of mortality among them.

Our best records have been made in the South. There is employment for one thousand more homœopathic physicians in the South alone.

It was first introduced in America by Dr. Gram sixty-five years ago. Despite prejudice and calumny, it has grown until there are almost 20,000 homœopathic physicians in the United States to-day.

Our fifteen colleges cannot supply the demand, "Send us a Homœopathic physician."

Koch's Treatment Condemned.

At a meeting of the Belgian Academy of Medicine on December 27, M. Crocq (*Semaine Médicale*, December 31, 1890) denied "absolutely" that Koch's fluid is of any value in the diagnosis of tubercle. He had made injections in a patient suffering from phthisis, and in another the subject of acute pleurisy, "without a trace of tuberculous character;" in both, intense reaction took place. In other cases of "manifest" tuberculosis the injections were followed by no reaction, while in other cases patients suffering from non-tuberculous affections reacted strongly. With regard to its alleged curative action, M. Crocq has seen nothing of it; in his experience the remedy has done nothing but aggravate the evil. The lymph is, according to him, simply a pyrogenic agent, and he "denies utterly" that it has any specific effect on tubercule. "It produces a febrile movement, of variable duration, which causes an effervescence of the organism, various congestions in the skin and internal organs which have no relation to any tuberculous lesion; this congestion is more easily set up in diseased organs which have previously been attacked by an inflammatory lesion of any kind, and form the *pars minoris resistentiæ* of every organism. If the patient is attacked by cutaneous or pulmonary tuberculosis, the inflammatory process will take place in the affected organs, skin or lungs." This pyrogenic action may be useful in certain cases in which "substitutive inflammation" (such as is seen, for example, in the effects of nitrate of silver on a chronic ulcer) is beneficial. This, according to M. Crocq, is the whole secret of the action of Koch's remedy. If the "substitutive inflammation" may possibly have a favorable effect in some cases, it may do harm in others, a new inflammation being added to the pre-existing one, with fatal results if the affected organ is the larynx or the lung. In short, M. Crocq says, Koch's statements as to the diagnostic and curative value of his remedy resolve themselves into simple gratuitous affirmations, unsupported by any proof.—*British Medical Journal* (Supplement), January 10, 1891.

Shaving with Vaseline.

As nurses often are called upon to provide shaving materials we recommend the following: "A friend of mine a few months ago told me how to shave easily and painlessly, and I have never shaved in a barber's shop since. The plan is to use oil or grease instead of soap to prepare the chin and soften the beard. Vaseline is the most convenient, and it should be rubbed in quite freely. Then with a keen razor shaving can be done quickly and without the suspicion of pain. At first I couldn't reconcile myself to doing without the orthodox lather, and used soap after the vaseline had been applied. But the soap is really unnecessary, and shaving with oil or vaseline is cleaner as well as pleasanter, and what is more to the point there is no irritation whatever to the skin."—*Druggists' Circular.*

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion."—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **C. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years.
Pronounced by connoisseurs unsurpassed for excellence and bouquet.

FRED'K DE BARY & CO., New York,

SOLE AGENTS IN THE UNITED STATES AND CANADA.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{500}$ gr.), Codeia ($\frac{1}{16}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{30}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

Clinical Lecture.

TREATMENT OF TYPHOID FEVER: TWO RELAPSES AND OTHER COMPLICATIONS. — ASTHMA ASSOCIATED WITH EMPHYSEMA AND CHRONIC BRONCHITIS.[1]

BY JAMES M. ANDERS, M. D.,

PROFESSOR OF CLINICAL MEDICINE AT THE MEDICO-CHIRURGICAL COLLEGE, VISITING PHYSICIAN TO THE PHILADELPHIA AND EPISCOPAL HOSPITALS.

Typhoid Fever.

The case before you is the one of typhoid fever, which you will recall was presented at this clinic last Wednesday. Girl, A. A., domestic, 23 years old. Her family history is unsatisfactory. Six weeks before her admission she was taken ill in Pittsburgh, improved, came to Philadelphia, and was soon after admitted to the female wards of the Philadelphia Hospital and found to be suffering with typhoid fever—most probably a relapse.

She had, as you will remember, three or four serious complications, one of which was hypostatic congestion, the result of a weak heart, which in turn was due to parenchymatous degeneration of the myocardium. She had had two hemorrhages from the bowel, and after the second hemorrhage, one was in a state closely approaching collapse.

About January 1, after recovering from her first relapse and after having had a subnormal temperature for about one week, she got up at night during the absence of her attendant, and ate heartily of candy, apples and cake. The next day her temperature was 104°, and this rise of temperature was followed by the other symptoms of the second relapse which was attended with moderately high temperature.

Errors of diet cause a relapse because of the latent virus still existing in the system. You will also recall the affection existing in the leg, which was swollen and painful to the touch. The swelling was localized over the middle third of the fibula and outer aspect of the os calcis, not due to thrombosis, but most probably to periostitis, or possibly to a pyemic condition; as small abscesses under the skin occur after typhoid fever. A pyemic condition has not, however, been developed. There exists tenderness only over the os calcis and outer third of the fibula. Making pressure over the fibula, we find it thickened and roughened as compared to that of the other side. There is pain developed, especially at night. Thickening of the bone, tenderness on palpation and pain at night are certain evidences of periostitis. As a rare sequel, it comes on two or three weeks after convalescence has set in; but it may occur during a relapse, as in this case. During the attack there has been some bronchitis and, later, pneumonia. You will recall the previous history; that there existed a feeble heart, which leads to hypostatic congestion of the lungs, and that there was no active bronchitis. The physical signs were: impairment of resonance on percussion and, later, crepitant râles.

During the patient's present or second relapse she developed pneumonia. In her case, in addition to the physical signs at the right base, there was rusty sputum, which indicated a lobar pneumonia. In patients much exhausted, as this one is, you do not have all the characteristic physical signs and symptoms of pneumonia. She has not the signs of collapse of the lung or bronchopneumonia. You are apt to have hemorrhagic infarction, especially where there is a pyemic condition, and when it occurs the emboli will lodge in the lower lobe of the right side. This is the result at times of

[1] Delivered at the Philadelphia Hospital.

venous thrombosis from feeble circulation, as you may remember, in her case during the former relapse. When pulmonary hemorrhage occurs, there will be dulness on percussion, feeble respiratory murmur and frequently bronchial breathing, with expectoration of a bloody or sooty-looking matter—not the characteristic sputum of pneumonia as in this case—with great pain. Another complication, which occurs once in about ten cases, is the albumin in the urine. In this girl's urine, it was found ten days ago in abundance. During her first relapse no albumin was found after repeatedly testing the urine. When considerable albumin is found during the course of a case of typhoid, it is good evidence of desquamative nephritis. During her first relapse the girl had four complications, and during her second relapse, three. The chief physical signs of the pneumonia have disappeared, but there still remains here some dulness and feeble respiratory murmur. The prognosis in relapse is good, provided the previous attack has been severe; but when the primary attack is mild the prognosis is bad.

When called to treat a case of typhoid fever, first place the patient in the largest and most airy room, with an open grate if possible; since this is preferable to a window as a means of ventilation. See that the sanitary arrangements are as perfect as possible. The leading indications calling for treatment are, to support the vital functions, to control the fever when high, and to arrest or modify the complications and sequelæ. As long as the temperature does not rise above 103°, there is, as a rule, but one object to fulfil, namely, to support the bodily functions. Attention must first be paid to the feeding. Food should be given at regular intervals of two hours each, and should consist mainly of milk. Should this be found to disagree, give it peptonized, that it may the more easily be assimilated. If it still disagrees, give, before each feeding, a mixture consisting of two grains of pepsin and five minims of dilute muriatic acid in syrup and water. Well-cooked farinaceous articles, such as barley, may be added to the milk; animal broths, in small quantities, may also be allowed. The system must also be sustained. This is best accomplished with quinine. If the temperature does not run high, two grains four times daily is sufficient. In the third week, gentle stimulation should be given, of about one-half ounce of either brandy or whiskey every four hours. In the severe forms, we must also diminish the fever and arrest complications and sequelæ. The reduction of the fever is sometimes imperative. This is best accomplished by the cold-water treatment. Do not be afraid to sponge the patient freely. Instruct the nurse to sponge in succession the face, neck, arms and chest as long as agreeable to the patient. If this does not suffice to bring down the temperature, use cold compresses, of ice-bags or cloths wrung out of cold water. Often, when placed to the head, this will reduce the temperature of the whole body, quiet the delirium and produce sleep.

If this does not suffice to reduce the temperature, place the cooling applications also on the stomach. Do not use the cold bath, unless the tub can be brought to the side of the bed, and only when the temperature is dangerously high or profound coma exists. Do not leave the patient in the bath longer than eight or ten minutes, and when he is taken out wrap him well in blankets, giving stimulants if he be exhausted.

In the way of internal antipyretics, do not use them unless the morning temperature is at or above 103°, no matter if the evening temperature should be 104°. If both morning and evening temperature is high, or if there be but slight remissions, you may resort to them early in the attack, if cold water does not suffice.

A number of remedies are advocated: antipyrin, antifebrin, phenacetin, salicylate of sodium, quinine, etc. Sodium salicylate disorders the stomach and sometimes causes albuminuria. Don't use it. I have found antifebrin, given in doses of two grains at night, to act as effectually as larger doses (ten grains for instance), and thus have avoided the danger from collapse. Phenacetin is said not to depress; but do not give it in large doses. When the temperature is dangerously high, then you may resort to heroic measures; indeed, this may be the only means of saving your patient. You may use the bath-tub, or rub the surface with ice, which answers the same purpose, or as a *dernier ressort*, give a large dose of some internal antipyretic.

The treatment of complications is all-important. Attend to the most urgent symptoms, one of which is headache; three grains of phenacetin, with twenty grains of sodium bromide, given occasionally will mitigate it. When there is distention of the abdomen,

do not use the hypodermic needle—use turpentine stupes. If this fails, give turpentine internally in emulsion. Diarrhœa, when prominent, should be treated with mild measures first; bismuth in full doses will generally control it, or a mixture of equal parts of tincture of catechu and paregoric gives good results. If it is not controlled in the manner stated, give one-quarter grain of nitrate of silver with opium, in pills every three hours, or two grains of acetate of lead every four hours, or suppositories of tannic acid and opium.

Of complications, perforation is the most serious, and requires active and timely treatment. In the books it is generally stated that opium is to be given in large doses; thus, metaphorically speaking, the bowel is placed in splints and peristalsis is arrested. This is unnecessary. Enough opium should be exhibited to relieve pain, and saline laxatives should be administered until a gentle movement is produced. Rochelle salts, in doses of a drachm every two hours, is the best for this purpose. Should thrombosis occur, elevate the limb, rub gently with vinegar and water or laudanum, and give internally stimulants, especially carbonate of ammonium. The pneumonia was here treated in the same way as the hypostatic congestion, because the indications were the same, namely, to stimulate and support well the patient. In this case, for the hemorrhages of the bowels, we employed ergotine hypodermically, and cold externally. Astringents may also be used for this accident.

With the above plan of treatment, you should not forget to disinfect thoroughly the stools. There is no longer any doubt but that the disease may be contracted through the lungs; hence it is well to have doors, floors and window ledges washed with some disinfectant in solution, or better still, after the patient leaves his room, to have it fumigated.

Asthma and Emphysema.

This man is 48 years old, and a sailor. His father died of pneumonia at 58, his mother of paralysis at 85 years. One brother died of asthma; another brother, living, has asthma. As a child this man had measles and scarlet fever. In India he had jungle fever. His present trouble began when he was 5 or 6 years old; at first the attacks of dyspnœa always came on at night, later they would occur during the day, the paroxysms increasing in severity. Between the attacks he would feel quite well. When young he learned the tanning trade, but early in life he gave it up, as he found it made his condition worse. Changing his occupation, he took to the sea and found the tropics agreed best with him. For twenty-five years he carried stramonium leaves with him, which he would steep in a solution of nitrate of potassium, burn them, and inhale the fumes. This gave him immediate relief; later, when the paroxysms increased in number and severity, the remedy lost its effect, until finally it lost control altogether. When in ports, he would obtain remedies from physicians for the attacks. For the last few years his condition has grown steadily worse. About the middle of November, 1890, he was shipwrecked at sea, where he remained three days without food and shelter.

Since then the attacks were notably increased, and he had them worse than ever. He stated that he has tried all the remedies ordinarily used, but they failed to relieve him. His last attack continued four hours, during which time he smoked stramonium constantly without good effect. January 11, when admitted to the Hospital, he was greatly cyanosed, his face, lips, nails, lids and eyes were blue, and his chest immovable. He was given at once nitrite of amyl by inhalation, with but momentary good effect; later he was given chloroform by inhalation, with but temporary relief. He was then directed by one of the residents to have tincture of conium, f℥ss, every half hour until four doses had been taken. When he had taken the third dose his breathing grew suddenly better. Obviously, the remedy deserves further trial. On admission his chest was as you see it now. It is greatly distended in all directions, is distinctly barrel-shaped. The neck seems short, from the chest being drawn up by the muscles of the neck, with marked depressions above the clavicles. The ribs are prominent anteriorly, and there is but little lateral movement of the chest in respiration. The stomach moves forward with each inspiration, which indicates a condition far advanced in emphysema. Percussion gives great hyper-resonance, almost tympanitic, while over the heart we get lung resonance. The cardiac dulness commences as low down as the sixth rib. Normally it should begin at the fourth, and there is only a very limited amount of dulness on account of the overlapping of the lung. The apex impulse is

lower than it should be. Below the costal border of the right side there is dulness, owing to the liver being depressed; and the lung resonance extends more than one inch lower than it should. In advanced cases of emphysema there is a marked degree of vesico-tympanitic resonance and great displacement of the heart and liver, as in the present case—a condition which is sometimes mistaken for pneumo-thorax. In the latter affection, you have, as a rule, the history of phthisis, of the occurrence of great pain followed by the signs of air in the chest. The breathing becomes at once difficult, the pulse rapid and feeble. Pneumo-thorax generally occurs on one side, though it may be bilateral, when it is more difficult to diagnosticate. The pain may be wanting, in which case, rely only on the physical signs in diagnosticating between this disease and emphysema. Inspection and palpation give the same result in both affections, except over the seat of effusion in pneumo-thorax, where vocal fremitis is wanting.

Percussion resonance in pneumo-thorax is more hyper-resonant, is frequently tympanitic; and where effusion occurs, a sharp line of dulness can be drawn at the level of the liquid, which line changes with the position of the patient. Over the seat of the effusion, there is flatness; but there is none in emphysema. On auscultation we get weak respiratory murmur, or the amphoric respiration and voice, which does not occur in emphysema; also metallic tinkling, and, on succussion, the splashing sound. In pneumo-thorax the heart and liver are usually displaced more than in emphysema, but rarely more than you see in the patient before you, suffering from emphysema. An enlarged heart may be mistaken for emphysema, because the apex is depressed; but the presence of clear percussion resonance over the heart, together with the symptoms belonging to emphysema, would aid in establishing the diagnosis. I want to lay stress upon the fact that you may have cardiac hypertrophy associated, and not be able to detect it.

The diagnosis of emphysema is almost certain when asthma is associated with it, as in this case. Here we have the history of asthma in the family, it being hereditary, which, however, is also the case with emphysema. The man gives us a clear history of chronic bronchitis, which began before the emphysema. The latter is probably due to the former disease. The prognosis, as far as immediate danger to life is concerned, is fair. The patient should be saved as much as possible from the exciting cause of asthma. A residence in a tropical climate would doubtless give him the best chance for increase of years.

As to treatment: It is necessary to prevent the degeneration of the air vesicles as much as possible by giving iron and arsenic in small doses, long continued. The ideal treatment would be to breathe into rarefied air and inspire condensed air. An instrument for this purpose can be obtained. The asthma should be treated with stramonium in cigarettes, and inhalations of chloroform; morphia hypodermically is an efficient remedy. Tincture of lobelia, gtt. x, every half hour, may be given during the paroxysms, if it do not cause too much nausea. Potassium iodide may be administered during the intervals, or the following recipe, when there is more or less active bronchitis and considerable expectoration associated with the emphysema, as in the present case:

℞ Syr. acid hydriodici . . . . . f℥ii
Syr. scillæ . . . . . ℥iss
Spts. chloroformi . . . . . ♏c
Syr. pruni Virgin. . . . . q. s. ad. f℥iv

M. Sig. Teaspoonful every three hours in water.

COMMUNICATIONS.

PRACTICAL USE OF THE METRIC SYSTEM.

A. L. BENEDICT, A. B., M. D.,
BUFFALO, N. Y.
ATTENDING PHYSICIAN, DEPARTMENT OF GENERAL PRACTICE, FITCH PROVIDENT DISPENSARY.

By an act of Congress, in 1792, a decimal system of currency was formally adopted for this country, necessitating the adoption of conceptions of value to a unit less than a quarter as great as the English pound, with which the people are familiar. For the last few years a decimal system of measuring drugs, established upon a scientific basis, with a simple and logical connection with other systems of mensuration, and already in practical use in other countries, has been awaiting recognition by the medical profession in England and in the United States.

The prime unit of this system is the meter, a line one-tenth millionth of the length of a quadrant of a terrestial meridian. A

cube constructed on the decimeter (one-tenth of a meter) is the unit of capacity, and is called the liter; it differs but little from our quart. The weight of one cubic centimeter of pure water at its point of greatest density, 40° C., and in a vacuum, is the unit of weight, and is called a gram. A liter, therefore, contains 1,000 grams of water and a little calculation will show that the gram is equivalent to about one-quarter of a drachm, or fifteen and four-tenths grains. In all metric scales the prefixes deka, hecto and kilo are used to form the names of units 10, 100 and 1,000 times the prime unit. The kilogram, for example, is equal to 1,000 grams, and it is the unit of weight in small commercial transactions, being equivalent to two and two-tenth pounds.

The prefixes deci, centi and milli indicate, respectively, one-tenth, one-hundreth and one-thousandth of the prime unit.

As far as prescription writing is concerned we need no other terms than gram, centigram and milligram, omitting the words decagram, hectogram, kilogram and decigram, just as in speaking of money we discard the words eagle and dime. For example, the expression 10.25, referring to money, would be read "ten dollars and twenty five cents," not "one eagle, two dimes and five cents." Occurring in a prescription, it would be read: "ten grams, twenty-five centigrams," instead of "one dekagrame, two decigrams and five centigrams." As we have to deal more with little things in medicine than in business, the milligram, unlike its analogue mill, in our money, assumes considerable importance.

The cubic centimeter, familiarly abbreviated and pronounced "c. c.," is often used as a liquid unit, corresponding to the gram. To avoid confusion with the centigram, it would be well to drop the expression "cubic-centimeter" and to use the word gram or fluid gram, instead. It may be remarked in passing, that the relation between the gram and cubic centimeter is nearly the same as exists between the grain and minim; but whereas the correspondence between the gram and cubic centimeter is scientific and exact, that between the grain and minim is merely approximate.

Advocates of the metric system often insist upon the dispensing of liquids by weight instead of volume. There can be no reason why the gravimetric, as opposed to the volumetric, method should be more closely linked with the decimal system than with the apothecaries' system. For purely scientific purposes, the weight of a substance is a more accurate expression of its quantity than the space which it occupies. On the other hand, our conception of the quantity of a liquid is more naturally connected with its volume than with its weight. The relation between the volume and the weight of a liquid is so little affected by the slight variations of temperature and atmospheric pressure in different drug-stores at different times; the loss by evaporation so far exceeds the greatest possible variation due to changes of temperature and pressure; the use by the patient of scales, or even of accurate measures in taking single doses, is so impracticable; and, lastly, our estimation of the proper dose of a drug is so much a matter of approximation—that an insistance on the less convenient method of dispensing liquid drugs by weight is very much like straining at a gnat after swallowing not only the camel, but a considerable portion of the rest of the menagerie.

What are the advantages of the metric system? Briefly speaking, the same as those which our decimal monetary system possesses over that of Great Britain. In detail they are:

(1). A simplification of the process of multiplication in constructing a prescription. (2). A simplification of the process of division in calculating from a complete prescription the amount of each drug given at a single dose. (3). The ease with which the proportion of drugs in antiseptic solutions, liniments, ointments, etc., may be indicated. (4). The use of units small enough to express conveniently the doses of very powerful medicines. (5). A close correspondence between our already existing conceptions of value as expressed in dollars, cents and mills, and the powerfulness of drugs as expressed by their metric dosage.

It is probable that an Englishman coming to this country will derive no immediate benefit from our system of money. Since he thinks in pounds, shillings and pence, it is of no advantage to him that cents can be converted into dollars by moving the decimal point; for before he can have a clear conception of the value of an article, cents must be converted into units with which he is familiar. So there is no benefit to be derived from the mere writing of prescriptions with Arabic figures and in terms of French units with which we are unfamiliar. Not until we can think naturally in the metric

system are we profited by its use. It is sheer nonsense for a man to write such a prescription as this:

℞ Argenti nitratis 13
Aquæ dest. 31.00

He is thinking of "two grains to the ounce," and it is quite likely that the druggist will fill the prescription, using the two-grain weight and the ounce measure. Not only is nothing gained by such "metric" prescribing, but there is the positive danger that, in the conversion from one system to the other, some error will be made. "Two grains to the ounce" represents a proportion of 1 to 240, or near 1 : 250. The prescription should, therefore, take the following form:

℞ Argenti nitratis 10
Aquæ dest. 25.00

In writing for medicine which is to be measured in doses, we must bear in mind the number of doses needed and the size of the measure from which the medicine will be given. The following table shows the relation between the ordinary dose-measures and the metric units:

One drop	.03
An old and worn teaspoon	3.50
A new teaspoon	5.00
A dessertspoon	10.00
A tablespoon, brimful	15.00
A tablespoon, heaped as much as the cohesion of the liquid allows	20.00

Suppose that we have to deal with a transient case of diarrhœa. We first set down the ingredients of our prescription without reference to the quantity to be given. We next decide upon the number and size of our doses. Ten doses will probably suffice, and a dessertspoonful (10.00) is a convenient amount for each administration. We therefore order enough of the vehicle to make 100.00. Our prescription is now in the following form:

℞ Ext. hæmatoxyli
Ac. sulph. arom.
Ol. cajuputi
Mucil. acaciæ
Syr. simplicem ad 100.00

To complete the prescription, we multiply the dose of each ingredient by ten. We may leave the amount of the mucilage to the discretion of the pharmacist.

℞ Ext. hæmatoxyli 2.50
Ac. sulph. arom. 5.00
Ol. cajaputi 2.50
Mucil. acaciæ . . . . . q. s.
Syr. simplicem ad 100.00

S. Dessertspoonful (= 10 c. c.) every three to six hours.

Most medicines will be given by the teaspoonful, and twenty or thirty doses may be conveniently dispensed at once. The teaspoonful may be reckoned either as four or five fluid grams. The use of the latter number is preferable, and, when accuracy is necessary, five fluid grams can be marked off on a test-tube by the apothecary. The ordinary mixture will, then, amount to 100.00 or 150.00 fluid grams.

The following prescriptions may serve as an illustration of the method of calculating a single dose:

℞ Ammonii chlor. . . . . 5.
Ol. eucalypti . . . . . 10.
Mucil. acaciæ . . . . . q. s.
Syr. pruni Virg. . . . . 50.
Aquam ad . . . . . 100.

S. Teaspoonful after meals.

℞ Calcii lactophos . . . . . 4.
Ol. morrhuæ
Mucil. acaciæ . . . . . āā 150.
Ol. amygd. amar. 10

S. Tablespoonful after meals.

The first prescription evidently consists of twenty five-gram doses. One-twentieth of 5 grams is a quarter of a gram, or 25 centigrams; one-twentieth of 10 is ½, or 50 centigrams; one-twentieth of 50 is 2½. The second prescription contains twenty doses each of fifteen grams. Half of each fifteen grams is cod-liver oil. Twenty centigrams of calcium lactophosphate are given at each dose, and half a centigram, or five milligrams of oil of bitter almonds. The last is rather a small dose, but the chief use of the essential oil in the emulsion is as a flavor.

Will the reader please contrast mentally the foregoing process of multiplying or dividing by 10, 20 and 30 with the corresponding multiplication or division by 12, 16, 24, 32, and the conversion of grains into drachms, and of drachms into ounces, or, *vice versa*, by the use of the numbers 60 and 8?

In prescriptions for external use, not only the amount but the proportion of each ingredient is plainly indicated. For example:

℞ Plumbi acetatis
Tinci sulphatis . . . . . āā 1.
Ext. hydrastis fl. . . . . 25.
Aquam dest. ad . . . . . 500.

Those who have been accustomed to remembering proportions as so many grains to the ounce should bear in mind that each grain to the ounce represents a strength of

about 1 to 500. In making antiseptic solutions, the physician will find in almost every household a close approximation to the 1,000 gram measure in the shape of a quart cup.

Only a few of the recently discovered alkaloids and glucosides can be given safely in doses of more than a fraction of a grain. The use of fractions is inconvenient in remembering the dose, in writing the prescription and in compounding it. The metric system, on the other hand, furnishes a unit, the milligram, so small that nearly all doses can be written in integers. To the best of the writer's knowledge there is no substance which could not be given to an adult with safety in a dose of half a milligram.

In our money matters we have not only the universally recognized unit but other amounts whose frequent use has elevated them to the position of auxilliary concepts of value. Many of these are spoken of in arithmetics as aliquot parts of a dollar. 2, 3, 5, 10, 12½, 15, 20, 25, 30, 33⅓, 50, 66⅔, 75, are examples of such values expressed in cents. 7, 11, 19, 47, etc., are examples of numbers to be avoided both in price lists and in dosage.

In becoming familiar with the metric system, it is well to group together, as far as possible, drugs of the same degree of *powerfulness*, and to think of the appropriate dose of a drug not merely as a quantity or weight but as a number which assigns to the drug its place in a scale. For example, if we pay twenty-five cents for an article we think of the twenty-five cents not merely as so much expenditure, but as an index to the value of the article when compared with the price of other similar articles. So, if the dose of a drug is 25 centigrams, we should think of the 25 centigrams, not as an arbitrary quantity, but as an expression of the *powerfulness* of this drug when compared with others. The following table of what may be termed dose values will prove useful in estimating the doses of other drugs which we may from time to time employ and the strength of which we know to bear a certain relation to that of the drugs mentioned :

.001—Atropine, hyoscyamine, hyoscine, physotigmine.

.002—Strychnine, picrotoxin, nicotine.

.005—Concentrated preparations of arsenic, gold salts, mercuric salts.

.01—Morphine, apomorphine, emetine, pilocarpine.

.02—Salts of copper, silver and zinc as nervines. Most of the poisonous extracts.

.05–.10—Most iron salts, codeine.

.15–.25—Most volatile oils, lead acetate, caffeine, acetanilide.

.25–.50—Ammonium carbonate and chloride, quinine, antipyrin, bismuth sub-nitrate and sub-carbonate.

1.00—Most hypnotics, salicylic and benzoic preparations, many moderately strong tinctures and fluid extracts.

2.–5.—Most tinctures and fluid extracts.

10.–15.—Syrups, infusions, etc.

10.–25.—Many saline cathartics, castor oil.

Although the metric system is best learned independently, those who are already familiar with the apothecary's system will need a scale of equivalents, and the following is approximately correct :

$\frac{1}{60}$ grain =	.001	ʒj =	4.00
$\frac{1}{3}$ " =	.01	℥j =	30.
3 grains =	.20	Oj =	500.
4 " =	.25		
15 " =	1.00		

In changing from the old to the new system, do not first write the prescription in the former system and then attempt to give its equivalent in the latter. After writing a list of the ingredients of the prescription, order the vehicle up to 10, 20 or 30 times 5. c. c. Then translate separately the single dose of each drug into metric terms, adding or subtracting a little if necessary to make the amount an aliquot part of the gram. Then multiply by the number of doses in the prescription. In this way—to borrow an expression from the teacher of languages—the metric prescription will be idiomatic and not a literal translation of one written in the old system.

The writer has been led to present this article because he realizes that many of the suggestions contained in it would have saved him much trouble if they had been available when he began to learn the use of the metric system. His own experience has been that one not too long accustomed to the apothecary's system can learn in a few weeks to use the metric system naturally and easily, and that its simplicity more than compensates for any difficulties which are met in the transition from one system to the other. A practical experience of nearly two years has shown him that, in Buffalo at least, pharmacists are invariably as well equipped to fill metric prescriptions as those written in the old system ; and that, while the medical men who use the metric system are in the minority, the minority is by no means insignificant, either in numbers or in influence.

TREATMENT OF CLUB-FOOT, PAST AND PRESENT.

BY LUCIA REDDING THOMPSON,

PHILADELPHIA.

A retrospective view has led me to compare the past and present treatment of club-foot, and to note a few of the many progressive steps which have given this wonderful century its pre-eminence. According to tradition, the custom of distorting the feet of Chinese women is a relic of an edict to render the deformity of an imperial child less noticeable by making the malformation common, thus confessing the impossibility of cure.

It is well known that Lord Byron abandoned any attempt at correcting his deformity after years of treatment. Previous to the time of Stromeyer, the treatment of club-foot was purely mechanical, and the orthopedic surgeon stood upon the level of the mere instrument maker, or upon the border line of empiricism. In the light of to-day, we can only pity those "cheated by dissembling nature deformed, unfinished, sent into this breathing world scarce half made up," at a time when men were afraid of the knife, and such measures as resection of the tarsus, tarsal osteotomy, open incision, tenotomy, etc., were unknown. With the development of antiseptic and aseptic surgery, radical measures have been adopted, and at the present time, few surgical procedures are more precise in their indications or more certain in their results.

The club-foot deformity is usually congenital, but it may be acquired after infantile paralysis, accident, or that inflammatory condition of the fibrous tissues about joints covered by the vague term "rheumatism."

Vague and various theories have been advanced in explanation of the congenital variety of club-foot. Maternal impressions, compression in the uterine cavity, lesions of the nervous system, etc. Heredity has also been strongly declared to be an etiological factor, and as such we must recognize it. At the same time we must admit that, though living in an age when all the symptoms of nature are exhibiting their mysteries, with ample facilities for investigation, the laws of heredity baffle the scientist, and we know no more than we know how it is that children inherit the features of their parents. We must admit that we are ignorant of the causation of club-foot, and unable to give an explanation of the phenomena of its development.

This position of the tarsal bones varies with the variety. In the congenital form, the scaphoid will be found articulating with the side of the head of the astragalus, rather than with the anterior surface. The cuneiform bones must follow from their close connection. The os calcis is usually found in the vertical position. The astragalus is so much distorted that it cannot be recognized by the most profound anatomist.

The only rational treatment consists of a combination of operative and mechanical means. The age at which treatment should be commenced is a matter of discussion. Many claim that operation should not be done before the end of the first year. Dr. H. Augustus Wilson, Professor of Orthopedic Surgery in the Philadelphia Polyclinic, advises early operation. As it is well known that in infancy and early childhood the ends of the bones are largely cartilaginous, it is therefore rational to believe that the sooner the foot is corrected the better. Prof. Wilson advises tenotomy with subcutaneous division of fascia, *in mild cases*, followed by some form of mechanical retention, until the bones adapt themselves to the normal position, and the muscles recover their tonicity. After operation, the foot should be placed in the corrected position by manual force and retained with a light plaster-of-Paris bandage.

In the New York *Medical Record*, Dr. A. M. Phelps reports one hundred and ninety-six cases treated by direct open incision since 1888. The advantages of open incision must be apparent. The surgeon becomes master of the situation, as he has every facility for complete division of all contracted tissues. Arteries can be spared by careful dissection, or cut and tied. In obstinate or inveterate cases, the ligaments should be divided; open incision renders this possible.

Dr. Thomas G. Morton's operation for club-foot cannot be too highly commended. He recognizes the astragalus with its forward dislocation as a check to the action of the joint, or as a foreign body, and therefore removes it. His results are good, as his series of cases at the Orthopedic Hospital will prove.

Again, for a moment, I would look backwards. Could a man of the last century have seen in a vision of the future the results of measures put into execution by men of this marvelous era, his heart would have

leaped, his nerves thrilled; for plainly he would have seen the hereditary curse lifted from those apparently condemned by nature. And instead of seeing behind the faint tinges of an expiring sunset would have seen all the glory of the daybreak decking the skies before.

GASTRIC ULCER.[1]

BY M. J. WEBER, M. D.,
LOWER PROVIDENCE, PA.

I purpose in this paper to call attention to an affection of the stomach, which, by its protracted course and the insidious manner of its development, along with the entire absence of any characteristic symptoms in many cases, often destroys life before the real nature of the malady is even suspected. I refer to gastric ulcer, the simple round ulcer of the stomach.

This disease, which is common in some parts of the continent of Europe and in England, is, according to Da Costa, comparatively rare in this country. Professor Welch states that he met with six cases of open ulcer of the stomach in about eight hundred autopsies. It has been my fortune to meet with two fatal cases of this disease, in which the diagnosis was verified by *post-mortem* examination; and two other cases in which I had diagnosticated gastic ulcer, one patient recovered under treatment, while the other passed out of my care and died, no autopsy being held.

Gastric ulcer may cause death in three ways: First, from perforation of the walls of the stomach and escape of its contents into the abdominal cavity; second, from perforation or erosion of blood-vessels and consequent hemorrhage; third, from gradual exhaustion.

Inasmuch as each of my two fatal cases represents one of these modes of death, a short history of each of them may not be uninteresting.

Case 1. Mrs. Y., seventy-two years old, while sweeping a bed-room was suddenly seized with a feeling of faintness, and immediately began vomiting bright red blood in large quantities. She sank to the floor and was lifted into bed. When I saw her, about fifteen minutes afterwards, she was vomiting partly coagulated blood profusely. I had some tincture ferri chloridi with me, which I gave her in teaspoonful doses, somewhat diluted, and the hemorrhage soon ceased. The woman vomited no more blood for four days, when the hemorrhage began again, and continued in spite of all treatment for three days, until she died exsanguine, seven days after the initial hemorrhage. In the four days during which she had no bleeding, she passed several dark, tarry-looking stools, which showed that blood had passed downward into the intestines.

The autopsy showed the stomach full of clotted blood, which, being turned out, revealed an open ulcer three-fourths of an inch in diameter on the posterior surface of the stomach, one and one-half inches to the right of the cardiac orifice and near the lesser curvature. On the anterior surface was another open ulcer, directly opposite the one on the posterior surface, and slightly larger, but not so deep. Close by the ulcer on the anterior surface, was a large cicatrix, which no doubt marked the site of an ulcer that had healed. The ulcer on the posterior surface had a hole in its floor large enough to admit a silver probe. This hole opened directly into the splenic artery, which was firmly adherent to the stomach at this point, and very calcareous. The cause of the hemorrhage was thus fully explained. The mucous membrane of the stomach and duodenum was thickened and dark red, and showed everywhere the marks of chronic catarrhal inflammation. The gall-bladder was completely filled with gall-stones. Over four hundred were taken out. This woman had never complained of anything more than a little regurgitation occasionally after meals, and the ordinary symptoms of dyspepsia. There had never been any biliary colic.

Case 2. Mr. K., farmer, sixty-nine years old, came to my office complaining of trouble in his stomach. He had walked about one-third of a mile, and seemed greatly fatigued. His symptoms for the last three years had been: partial loss of appetite, a feeling of uneasiness and fulness in the stomach after eating, constipation, flatulence, heartburn and eructations of gas; in short, all the symptom of chronic gastritis. There had never been any great pain in the stomach, nor any vomiting or hemorrhage. His symptoms during the last year had been gradually growing worse, and during the last twenty-four hours he complained of

[1] Read before the Montgomery County Medical Society.

considerable pain in the epigastrium, and felt very ill in general. His tongue was coated, his pulse was 90. Percussion over the abdomen elicited great tenderness in the epigastric, umbilical and right hypochondriac regions. This tenderness was so great that a satisfactory examination could not be made. I diagnosticated a local peritonitis, caused most likely by a perforating ulcer of the stomach or duodenum, and advised the patient to go to bed, setting forth the gravity of his condition, and prescribing opium for him. He went home, but did not go to bed, and the next day I found him sitting in a chair, vomiting frequently, and complaining of pain over the whole abdomen. He now had the symptoms of a general diffuse peritonitis. Eight days afterwards he died. The autopsy revealed a diffuse peritonitis, the intestines being matted together and adherent to the whole anterior surface of the abdomen. Examination of the stomach revealed an open round ulcer one and one-fourth inches in diameter immediately adjoining the pyloric orifice, and on the lesser curvature. The edges of the ulcer were thickened, and a perforation in its floor communicated with its peritoneal cavity.

The history of these two cases shows how serious a disease gastric ulcer is, how insidious and protracted may be its course and how great is the importance of its early recognition.

It is not my intention, in this paper, to enter into any detailed consideration of this disease. A short description will suffice.

The characteristic symptoms of gastric ulcer are pain, hemorrhage from the stomach, vomiting and disturbances of digestion. Pain is the most constant symptom, and it usually becomes more acute within a half hour after eating. Many cases of ulcer of the stomach occur, however, which present nothing but the symptoms of chronic gastritis. Gastric ulcer occurs with greater frequency among women than among men. According to Dr. Brinton the proportion is two women to one man.

The cause of gastric ulcer is obscure. Abercrombie and Cruveilhier believed it to be the result of chronic gastritis. Rokitansky and Virchow assign its origin to a local embolism or thrombosis. Riegel ascribes the chief cause to a constant state of hyperacidity, while Engel held that gastric ulcer was not due to any one cause, but might originate in a variety of ways. This was also Brinton's view.

Gastric ulcers occur mostly on the posterior wall of the stomach, on or near the lesser curvature, and usually near the pylorus. They are usually round, and if recent have sharp edges and look as if a circular piece had been cut out with a punch. Old ulcers, however, become somewhat irregular, the greatest loss of substance being in the mucous coat.

The duration of gastric ulcer is variable. It may exist for years before causing much trouble, and a fatal termination may occur within a few days after the initial lesion. Brinton states that he had a case under observation for thirty-five years, while Niemeyer relates the case of a physician who died from a perforating ulcer of the stomach eight days after he felt the first symptoms. Probably from three to five years is the average duration. In the second of the cases I have described the ulcer certainly existed for three years.

In many cases of gastric ulcer the diagnosis is easy, while in other cases it is impossible or amounts only to a suspicion. The two diseases with which gastric ulcer is most likely to be confounded, in the absence of a tumor, are nervous gastralgia and chronic gastric catarrh. In case of doubt, however, it is best to put the patient for a time on the proper treatment for gastric ulcer.

What should be the character of the prognosis in this affection? It seems to me that, in view of the danger of sudden perforation or severe hemorrhage, the prognosis should not be too favorable. Then, too, cases often relapse after recovery has begun. The case mentioned above as having ended in recovery, relapsed about six weeks after treatment was begun. The patient thought she was well, went visiting and ate heartily of beans, cold-slaw and ham, and all her former symptoms returned. Two months more of careful treatment cured her.

In treating gastric ulcer, diet is very important. We should seek to remove all sources of irritation from the ulcer, so that the process of repair may go on uninterrupted.

This may be accomplished by giving the stomach complete rest and nourishing the patient entirely with nutrient enemata. This method of administering food, however, presents many difficulties in practice, and I believe is rarely required. By a proper selection of the diet, the patient can be more satisfactorily nourished by the stomach,

without interfering with the healing process.

The most valuable article of diet in this disease is milk. Under an exclusive milk-diet, the pain and vomiting cease and cicatrization takes place. The patient should take from one to two quarts a day. Where plain milk disagrees, peptonized milk may be tried. This preparation has proved exceedingly valuable in the treatment of gastric ulcer. After three or four weeks, meat broths, farinaceous foods, soft-boiled eggs, etc., may be given. For at least three months the patient should be confined to easily-digested food; and when there is reason to believe that the ulcer is healed, the usual diet may be gradually resumed.

The drugs most used in the treatment of gastric ulcer are subnitrate of bismuth and nitrate of silver. I have carried out Trousseau's plan of giving these drugs in succession every two weeks, with success. By this method the danger of causing argyria is averted.

The best way of relieving the pain of gastric ulcer is by the use of opium in some form; but, in prescribing opium in this disease, the physician should not forget the danger of establishing the opium habit. Besides this, opium retards digestion and increases the constipation already present.

The treatment of complications, such as vomiting, hemorrhage, dyspepsia, etc., is the same as when they occur under other circumstances.

For the relief of the constipation, I found no drug or combination of drugs to answer as well as maltine with cascara sagrada.

RECENT MEDICAL JURISPRUDENCE.

HENRY A. RILEY, ESQ.,
NEW YORK.

A recent case in New York is of much interest to physicians, as it bears on the question of collecting bills. In this case, the physician seems to have been at fault, and the Court refused to come to his aid.

The circumstances were as follows: The mother of a patient went to the physician and paid him the amount asked for on account of his services, and received a receipt "in full for medical services." The mother had requested the services, and was understood by the physician to be acting for the patient in making the payment. The latter, however, did not authorize the payment. The physician afterwards brought a suit against the patient, to recover a further amount, claiming that the services were worth more than he had received. There was no satisfactory explanation given of the receipt in full, and the physician did not show that the receipt was, in fact, for part of the services, instead of them all. The Court held, on this point, that the receipt in full was *prima facie* evidence of payment for everything, but was subject to explanation showing a misunderstanding. The physician failed to show this, but relied mainly on the testimony of experts to prove that the services were really worth more than he had received. The Court refused to be influenced by such testimony, and said that when the amount due had been adjusted and paid, the opinions of other persons, that the services were worth more than this sum, could not be considered. I have no doubt that this decision is good law in other States than New York, and it certainly is good sense.

The present cold snap will no doubt cause many accidents from slipping on the ice and snow, and the sufferers will certainly be anxious to sue some one and recover damages for their pain and grief. Most persons, in such circumstances, decide to sue the city or town authorities, rather than the owners of the properties in front of which the accidents occur. These suits are brought on the theory that the city or town is responsible for the care of the streets, and must keep them in a passable condition or suffer the consequences. The Courts recognize and enforce this general rule, and, as a result, there are many actions brought and many judgments secured. There is a limit, however, to the responsibility for sidewalk accidents, and the city cannot be made to pay for every slip and fall. In a recent case the limitations are thus stated: "The duty resting upon municipal corporations to remove accumulations of ice and snow as it falls from time to time upon their streets is a qualified one, and becomes imperative only when dangerous formations or obstacles have been created, and notice of their existence has been received by the corporation. Actual notice to the public authorities is not in all cases required, and it has been held that negligence may be inferred from the omission by the corporation to cause dangerous obstructions to be removed from the streets, after sufficient time has elapsed to afford a

presumption of knowledge of their existence and an opportunity to effect their removal."

In a late criminal case in Kentucky, the Court was called upon to decide whether oral evidence could be introduced to prove the contents of a written statement made by the injured man when in expectation of death. The accused person had in some way destroyed or concealed the written statement, and it was held that in such a case oral evidence was perfectly proper. The Courts are, however, careful to require the best evidence to be produced, and this, in ordinary circumstances, would be the original statement and not a copy or any recollection of its contents.

The rules governing expert evidence are quite strict, and physicians are not allowed to give their opinions, except upon statements of facts which are clearly given and cannot well be misunderstood. In a late New York case, it was held that an expert could not be asked whether, in his judgment, "based on all the testimony" and "on the whole case," a criminal was sane or insane, as the jury would not be able to tell upon what facts the witness based his opinion. The proper course is for the counsel to frame hypothetical questions stating exactly certain facts, assumed to be proved, and then to ask the witness his opinion, based on such facts. An expert witness cannot be asked his opinion, founded on what he has heard other witnesses testify.

Veterinary surgeons are held liable to the same requirements of care and knowledge that members of the medical profession are subject to. A recent suit in Nebraska brings out clearly the law bearing on such cases. The Court said: "A veterinary surgeon impliedly engages and is bound to use, in the performance of his duties in his employment, such reasonable skill, diligence and attention as may be ordinarily expected of persons in that profession. He does not contract to use the highest degree of skill, nor an extraordinary amount of diligence, but to exercise a reasonable degree of knowledge, diligence and attention."

The Iowa Code seems to open a possible opportunity for injustice to insane persons by not requiring their presence at examinations into their mental condition. A recent case states that if the Commissioners of Lunacy, after preliminary inquiries as to the condition of one sought to be adjudged insane, shall be of the opinion that his presence, during the investigation, would be injurious to him or without advantage, they may dispense therewith.

There does not seem to be any requirement of a personal notice that the examination is to be held, and it would appear that a person can be declared insane, who does not know that any proceedings are on foot for such a purpose.

Periscope

Koch's Remedy.

The *Johns Hopkins Hospital Bulletin*, January, 1891, contains a very discreet report by Dr. A. C. Abbott of the impressions made upon his mind by a visit to Berlin, to investigate the use of Koch's remedy for tuberculosis. In this report, Dr. Abbott says: I shall not attempt to give in detail an account of the cases which were seen by me but shall present the general conclusions at which I arrived. Judging from the cases which I had the opportunity of seeing, I feel justified in concluding that the outlook for those coming under the head of "surgical tuberculosis" is a very favorable one. In the lupus cases particularly, one may say that up to date cure has certainly been effected in a fair number. These cases, as was pointed out by Koch, present altogether the favorable material for the observation of both the systemic and local reactions following the injections and, as a rule, respond in an astonishingly rapid manner to the treatment.

In the group of surgical cases coming under the head of "joint tuberculosis" the injections of the virus have not rarely been continued until the systemic reaction practically ceased to appear even though large doses may have been reached, and still the local expression may have improved but slightly or not at all. In one such case that I call to mind the joint cavity was subsequently opened and it was found a mass of necrotic tissue containing tubercle bacilli. This tissue was lying free in the cavity and had been thrown off from a point on the wall of the joint which still presented the characteristics of tuberculous tissue.

In a second case which I saw demonstrated there was every reason for believing that the condition was identical with that of the joint to which I have just referred.

At operation, however, there was a conspicuous absence of anything in the joint that would lead one to suspect the presence of offending necrotic tissue. At the point, however, on the cartilage was an old scar, evidently of tubercular origin, and it is not improbable that the irritation of and effusion into the joint may have resulted from the local reaction in this bit of scar tissue; a reaction analogous to that seen in the scar tissue of the skin which remains after surgical operations for the removal of underlying tuberculous processes.

In the joint troubles of this character the best results which may be expected will be those arising from the action of the virus, combined with the treatment of the joint by the ordinary surgical measures.

It is as yet impossible to say what the result of the treatment in the pulmonary manifestations of the disease will be. Evidence in this department accumulates so very slowly that one is hardly justified in speaking confidently as to the results.

The employment of the agent in laryngeal cases of tuberculous nature should be conducted with the greatest care, and the treatment should begin with even a smaller quantity of the agent than that ordinarily employed as the minimum dose for other troubles. The conjestion brought about in the tissues of this organ as a result of the treatment may plainly be seen to be of a dangerous, if not a of fatal, nature.

As is well known, Koch has said positively that phthisical patients in whom the disease is but only slightly advanced can be cured by the systematic employment of the virus. In his experience this class of patients were in a number of instances pronounced as cured after from four to six weeks. He claims further that a patient in whose lungs cavities of limited extent exist may be very much improved, and indeed almost cured by this method.

It has not been my province as yet to see any of the cases which have been reported as cured, though I have seen a number in which the tubercle bacilli were said to have disappeared for longer or shorter periods of time from the sputum of the patients.

From my personal experience in the wards in which the pulmonary cases were being treated, I feel constrained to say that, in my opinion, it is only with the greatest conservatism that one should express an opinion as to the result of the treatment. There is no doubt that many of these patients gave evidence of improvement, but for one to say positively that they were cured would, I believe be, at present, a little premature.

In concluding his report, Dr. Abbott expresses the opinion that the outlook in surgical cases of tubercular nature is good, particularly in those most superficially located; that, in the lung cases, the outlook appears to be fair if the cases are treated sufficiently early. For advanced cases he thinks it would be premature to do more than speculate, in view of the existing evidence. The intestinal cases, so far as they have as yet been observed, he thinks are unpromising.

New Remedies for Whooping-cough.

In the *Deutsche med. Wochenschrift*, January 19, 1891, Boas gives an interesting review of some new remedies for whooping-cough. Antipyrin was first used by Genser, who reported his experiences with 120 cases. The average duration of the disease was twenty-four days, as compared with the usual sixty to ninety days. Genser gave, as a dose, one and a half grains for each year of the child's age. Sonnenberger reported upon 70 cases. To young children he gave doses of from half of a grain to one and one-half grains three times a day; to older children, from two and a half grains to fifteen grains. He observed marked lessening of the severity of the attacks and shortening of the duration of the disease. Antipyrin is by no means always harmless, it appears, and there are a number of cases of poisoning from its use. Rothe, who has observed unfavorable results from the employment of antipyrin, uses a combination of tincture of iodine and carbolic acid, and proclaims its great advantages. Of a hundred cases upon this treatment he could recollect none in which the disease lasted longer than four weeks. He makes use of the following solution:

℞	Acidi carbol.	gr. iss
	Alcoholis	♏iss
	Tinct. iodi	gtt x
	Tinct. belladonnæ	gtt xxx
	Aq. menth	f℥ii
	Syr. opiat[1]	♏xv

M. To children over two years of age, a teaspoonful every two hours.

Antifebrin has also had advocates. The

[1] Contains, according to Ewald, only about 1½ hundredths of a grain of extract of opium.

dose is from one-half to four and a half grains, three times a day, according to the age of the child.

Heiman employed phenacetin in a case in which antipyrin had failed, and the result was so surprising that he employed it in two other cases. It diminished the number of the attacks from fifteen to three, and for a day at a time they ceased entirely, but returned at night if phenacetin was not given. The dose for a child three years old was one and a half grains three times a day.

Moncoroo, in 1885, was the first to recommend resorcin locally in whooping-cough. His results have been confirmed by others.

The fumes of sulphur have been recommended by Manby and Weissberger. The latter speaks enthusiastically of the remedy. He burns morning and evening one hundred and fifty grains of sulphur and exposes the child for an hour to the vapor. The gas generated is not concentrated enough to more than provoke a slight irritation of the throat and nasal mucous membrane.

Stepp recommends bromoform, which is given in drop doses in water. A child three to four weeks old receives one drop three or four times a day, older children in proportion. One hundred cases are reported and no disagreeable symptoms have been observed. Recovery resulted in from two to four weeks. Care is required on account of the volatility of the bromoform, because it is easily decomposed. It should be kept in dark bottles. Löwenthal confirms Stepp's statements, and also reports one hundred cases. The highest quantity taken (during the course of the disease) was five drachms, the lowest seventy-five minims; the separate doses were the same as those employed by Stepp. In a few cases Löwenthal observed weariness and sleepiness after giving the drug, and in one case, probably on account of too large a dose being given, poisoning occurred, but it was quickly overcome by stimulants.

Neumann reports that the bromoform has a favorable influence, but it does not shorten the attacks decidedly. Louis Fischer's experience with it has also been very favorable.

Schilling has experimented with chloroform water in the form of inhalations: a teaspoonful of warm water is put into the receptacle of the inhalation apparatus and chloroform added in drops according to the age of the patient. The sitting is ended as soon as the water, converted into steam by heat, has been used up. Four sittings are given a day. These inhalations act favorably upon the attacks and upon the duration of the disease. Sixty-two cases are reported.

Manasse recommends, upon an experience with forty-one cases, terpin hydrate, which is administered according to the following formula:

℞ Terpin hydrat. . . . . gr. viiss–xv
In. pulv. No x.
Sig. One powder three times a day.

Improvement is said to occur with certainty in four or five days. Manasse reports a favorable influence especially upon the bronchitis which is nearly always present. Digestion is in no way influenced by terpin hydrate, and it has no systemic action. Telamon recommends terpin hydrate with antipyrin:

Terpin hydrat. . . . . gr. xv–xxiii
Antipyrin . . . . . gr. xv
Syrupi aurantii cort. . . . . f℥iss
Aq. Liliæ (Linden) . . . . . f℥ij
M. Sig. One to two coffeespoonfuls several times a day for a child from one to four years old.

A very new remedy is ouabaïne, an alkaloid obtained from a root used by the Somalis as an arrow poison. It is recommended in whooping-cough by Gammel. One-twentieth of a milligram is the dose. The results obtained by its use thus far have not been brilliant.

A Failure with Koch's Remedy.

The *New York Medical Journal*, February 14, says: A significant case was reported at the last meeting of the New York Pathological Society, on Wednesday evening, that seems to us to go far to exemplify the force of the cautions inculcated by Virchow's observations, subsequently re-enforced by Henoch's, as to the possibility of spreading or intensifying a moderate tubercular invasion by the employment of the Koch treatment. The case was that of a man presenting the rational and physical signs of pulmonary tuberculosis, but in whom no pulmonary cavity could be detected. After he had been given twenty-four injections of Koch's liquid, in the usual doses and at the usual intervals, the number of bacili in the sputum was found to have increased, and the patient's condition was decidedly worse. A cavity was detected in the apex of the lung, and the patient died shortly after the discontinuance of the Koch treatment. After death, the cavity was found in the lung, about as large as a lemon, and there was

miliary tuberculous disease of the lungs. The tuberculous foci were surrounded by intense congestion, and the meninges of the brain and various organs were also highly congested. The opinion was expressed that at the outset the case was eminently a proper one for testing the efficacy of the Koch treatment.

Cremation and its Safeguards.

The *Lancet*, January 31, 1891, says: Unfortunate circumstances connected with the death of the late Duke of Bedford have brought into prominence an important question respecting the procedure of the Cremation Society, of which the late Duke was a prominent member, in cases of death from other than purely natural causes. It is clear that in the case of the Society absolute certainty as to the cause of death when other than natural can alone justify the preferential application of its method. It will therefore be interesting to examine the practical value of the safeguards adopted by the Society to prevent the chances of fallacy in a matter so important. These are three—namely: (1) the certificate of the medical practitioner in attendance on the deceased during his last illness; (2) a second independent certificate by another practitioner after careful inquiry into the circumstances attending the illness; and (3), should any doubt remain, the evidence afforded by necropsy. A further, though possibly less permanent, security exists in the resolution of the Society to refuse cremation in any case where the least doubt exists respecting the cause of death. Such doubt, as observed by Sir Henry Thompson, could remain after necropsy only in an extremely small number of cases, and would, in fact, be virtually abolished. Not actually so, however. There still remains a minimum uncertainty, and this, it is apparent, is much greater where certification even on the very careful system employed by the Society, is alone relied upon. The practitioner in attendance might, in spite of diligence and skill, be misled—for example, in a case where the signs of poison were obscurely blended with those of real or supposed disease. In this connection the case of the late Mr. Maybrick is suggestive. Is it then to be believed that a second medical testimony, which would be independent of the former, could be relied on to guarantee the difference of opinion which would necessitate an appeal to the coroner? We should rather expect that this latter evidence, divested as it must be of various technical premises which guided the statements in the first certificate, would be at best a carefully weighed and usually confirmatory assertion of moral certainty. After all it is probable that the most reliable safeguard against a too precipitate practice of cremation which we possess is to be found in the resolutions of the Society above mentioned. Cremation therefore under its present rules is certainly a valuable means of promoting accuracy in certification. As affording an absolute guarantee of such accuracy it cannot be depended on, while it must in all cases destroy every trace of morbid or mischievous agency contained in the tissues. While therefore we freely admit its practical security against any miscarriage of justice in the vast majority of cases, we cannot admit that it stands in this respect on a level exactly so high as the practice of burial. Moreover, while we also recognize its more absolute and destructive purity in the disposal of infectious dead, we do not see that it possesses any such advantage in comparison with burial in other cases, provided that burial be conducted, as it increasingly is conducted, on a rational or "earth to earth" system.

Treatment of Tuberculous Abscesses with Hot Water Flushing.

Mr. Arthur E. Barker, Surgeon to University College Hospital, says, in the *British Medical Journal*, February 7, 1891: Hitherto the usual treatment of large tuberculous abscesses, whether connected with a diseased spine, with broken-down glands, or in the soft parts, has left much to be desired. Whether they were simply allowed to burst, or were opened and dressed antiseptically, or whether they were aspirated with or without subsequent injection of germicidal fluids, the results have often been far from satisfactory. Either the discharge, however sweet, has gone on for an indefinite time through open sinuses, or the abscess has become infected with saprophytic organisms, and only too often with acute septic processes.

Having had considerable experience in the removal of tuberculous material from widely diseased hip-joints with hot water flushings applied in a special way, and hav-

ing seen case after case heal completely and permanently without any drainage, under one dressing, after such treatment, I have been encouraged to apply the same method to large tuberculous abscesses elsewhere. The results have exceeded expectation, and have encouraged to further trial.

The *modus operandi* is simply this: Take the case of a psoas abscess, in which the bone lesion is apparently stationary, or perhaps healing, but where a large collection is steadily, though slowly, advanced towards the skin of the thigh. In such a case a two-inch incision is made through sound structures over the lower end of the swelling. Through this opening a hollow gouge is inserted, which is connected with a reservoir of hot water at 105° to 110° F. by a rubber tube some 6 feet long. This reservoir (a 3-gallon can) is raised about 5 feet above the operating table. When the water is now turned on it rushes through the long gouge to the fundus of the abscess with considerable force, and the reflux carries the contents of the cavity out by the incision. By gently scraping with the flushing scoop the more solid caseous matter is dislodged, the hot water carrying it clear out of the cavity at once. Then the walls of the cavity are gently scraped in a methodical manner until the soft lining is loosened and carried away from every part of the abscess. In order to effect this thoroughly I have had these scoops made of varying length, so that the deeper parts can be reached. In the case of a psoas abscess they can be carried up under Poupart's ligament nearly, if not actually, to the spine. In using them all violence must be avoided, lest important structures should be torn, or lest the fibrous wall of the abscess should be broken through, and, finally, to avoid bleeding. With hot water the bleeding is but slight if the peeling be done cautiously.

When the water runs out clear after having been carried to all recesses of the cavity, the instument is withdrawn. Then any excess of water is squeezed out, and if the deeper parts are accessible, sponges are used to dry out the last traces of moisture. Then two or three ounces of fresh iodoform emulsion are poured into the deepest part of the abscess, and stitches are inserted in the edges of the incision. Before these are knotted all excess of emulsion should be squeezed out of the cavity. The knotting of the silk sutures then completes the procedure. As no drain tube is used at all, a simple dry dressing of salicylic wool is alone required, but it should be laid on in considerable quantity, so as to exert elastic pressure over the whole area of the abscess when bandaged. Such a dressing may be left on for about ten days, when it is time to remove the stitches, and the wound should then be firmly healed. A piece of salicylic wool secured by collodion at the edges should, however, be laid over it to keep it from chafing for a few days longer, and the elastic pressure should also be kept up.

Such a procedure is only demanded for the larger tuberculous collections, such as, for instance, psoas, iliac and lumbar abscesses. Of course, for those that can be fairly isolated, no treatment is better than to dissect them cleanly out without rupturing them—a practice I am very partial to. This can be done in perhaps a much larger proportion of cases than is commonly supposed, even when the contents are fluid. Again, in the case of softening tuberculous glands, it is the proper thing to dissect round them and remove them entire, and wounds thus made ought to heal by first intention and without drainage. Some of the larger abscesses, such as those alluded to above, may also ultimately be cured by aspiration of their contents and injection of iodoform emulsion. But in my own experience of many such cases this requires considerable time, is uncertain, and is only to be achieved when the contents are very fluid. Where there is much solid matter which will not pass through the needle, I know no method so reliable and so speedy as that of mechanical hot water flushing. I have always called this "flushing," as it is something totally different to mere irrigation, which does not carry away the material one is anxious to have removed.

Massage as a Cause of Pyemia.

In the *Vratch*, No. 21, 1890, p. 474, Dr. Petr S. Novitzky, house-surgeon to the Kazan Military Hospital, records a very instructive case which proves that massage of a suppurating gland can easily give rise to the so-called "multiple or metastatic pyemia." A shopkeeper fell ill with suppurative inflammation of his right parotid gland. On the sixth day of the disease, he energetically rubbed into the fluctuating tumor some gray mercurial ointment. In a few minutes there appeared severe rigors, while the swelling markedly decreased in bulk. In the course of two days there developed

several abscesses (varying in size from a nut to a pigeon's egg) on the right side of the scalp and neck and in the right submaxillary region. On the fourth day (after the rubbing in), the left major pectoral muscle became inflamed. On the tenth, a large abscess on the right calf made its appearance. On the seventeenth, the right lung was found affected. On the twentieth, the patient died of exhaustion. According to Dr. Novitzky's theory, the energetic manipulations, made by the man on rubbing in the salve, had driven pus from the parotid abscess into the adjacent lymphatic and blood-vessels. Pointing to his case, the author earnestly warns against practicing local massage in cases of suppurative parotitis or mastitis (which method has been recently recommended by Dr. Zemblinoff, of Usman, in the *Vratch*, Nos. 3 and 7, p. 61).

New Remedies for Ear Diseases.

Dr. Edmund Szenes, an otologist of Buda-Pesth, lectured before the Imperial Society of Physicians at Buda-Pesth, June 14, 1890, upon the therapeutic value of some new remedies introduced into the practice of ear diseases, and Dr. Patrzek makes a report upon this lecture in the *Allgemeine med. Central-Zeitung*, January 3, 1891.

Menthol, according to Szenes, has proved of value in the treatment of furuncles of the auditory canal. A twenty per cent. solution of it is used, and a pledget of cotton wet with it is placed in the canal. A twenty per cent. solution of aceto-tartrate of aluminium is likewise of good service. In using it, patients are directed to fill the auditory canal every three hours with a warmed solution, and to keep it in the ear for some minutes. Kirchner has recommended the following solution for furuncles:

℞ Corrosive sublimate . . . . . gr. ¾
Water . . . . . f℥i
Glycerine . . . . . f℥v

He alludes to staphylococci detected by him in the secretion of the furuncle. Szenes says the sublimate acts best after incision or spontaneous opening of the furuncle. Szenes has also employed acetate of aluminium, which is much prized as a remedy in furnuculosis of the auditory canal. It is diluted four times with water. It allays the pain but does not shorten the course of the disease process. During the last epidemic of influenza, in the first stage of acute inflammation of the tympanum, a fifteen per cent. solution of carbolic acid in glycerine did good service. Szenes is not enthusiastic over creolin; all antiseptic fluids which are not clear should be banished from ear practice. Iodol, which has been recommended in place of iodoform, accomplished no results in otorrhœa, notwithstanding its daily use for several weeks; and salicylate of bismuth and aristol were of as little service.

Szenes has the following to say about the much-used treatment with powdered boric acid: "When the perforation in the drum membrane is sufficiently large, and occupies a convenient position; when there is no caries of the ossicles, or of the tympanic wall; when, moreover, no affection of the mastoid exists, and when, therefore, no retention of pus and its effects are to be feared, then, after proper cleansing and drying of the tympanum, a little boric acid can be blown into the deeper parts of the external auditory canal."

Lactic acid, even in weak solution, causes pain and erosions, so that soon it has to be given up. Cocaine, recommended by Kiesselbach, for tinnitus, has in no case proved effective. At the Prague ear clinic of Prof. Zaufal, Szenes saw massage employed, and he praises its effect in diminishing pain and promoting absorption. The hand is anointed with iodine ointment and the mastoid and the region behind the ante-tragus is stroked downwards, on the side of the neck, and as far as the clavicle.

Lupus and the Koch Fluid.

After brief references to the enthusiasm which the first announcements of Koch as to his remedy for tuberculosis aroused and to the reaction which has set in, accelerated by the reports of Virchow, Dr. Hermann Isaac, of Berlin, in the *Deutsche Medizinal Zeitung*, January 19, 1891, discusses the utility of the remedy in the treatment of lupus. While in the case of tuberculosis of internal organs, the most cautious dosage and careful observations cannot obviate occasional untoward results, experience teaches that the remedy exerts its specific curative influence especially in tuberculous processes of exposed surfaces. In the case of lupus no obstacle is interposed to the extrusion of the structures cast off as a result of the action of the injection of the Koch fluid. An important

consideration in the treatment of lupus in this way lies in the fact that the patients are usually otherwise robust and healthy. So striking is this that there are yet distinguished dermatologists who do not admit the identity of lupus and tuberculosis. Isaac, however, considers the reaction with the Koch fluid to decide the tuberculous nature of lupus.

Dr. Isaac observes the precaution to make the initial injection one milligram (.001). A boy of thirteen, with lupus of the left cheek, reacted typically to a half a milligram (.0005). An elderly woman with lupus of the upper lip of forty years' standing was much improved after having received ten injections. At the same time she was relieved of distressing dyspnœa arising from emphysema. Marked general reaction occurred in a case of lupus erythematodos after the injection of eight milligrams (.008). No local reaction was apparent, although the efflorescences receded after repeated injections. Two other cases of lupus reacted locally to one milligram (.001) of fluid, while the general condition was but little affected. In doubtful cases, involving the diagnosis of lupus from carcinoma, syphilis and some forms of eczema, Dr. Isaac thinks the remedy is invaluable.

Internal Lavage.

A few years ago, perhaps based on the fact of the deficiency of chlorides in the urine in pneumonia, it was proposed to treat this disease by subcutaneous injections of large quantities of water containing, in solution, sufficient common salt to approximate the specific gravity of the fluid to that of the serum of the blood. It was found that these injections were well borne, to say the least, and a number of the cases thus treated recovered. Now, M. Sahli, of Berne, in the *Bulletin Médical*, January 25, 1891, proposes to apply the procedure, which he calls "internal lavage," to the treatment of certain morbid states, such as typhoid fever and uremia, in which auto-infection plays a prominent rôle. The theory is that the tissues are flushed by the fluid, which carries off the noxious agents through the kidneys.

The apparatus for this method of treatment consists in a reservoir to contain a sterilized saline solution, a rubber tube, and a large, hollow aspirating needle. The needle is introduced into the subcutaneous connective tissue of the thigh or buttock, and the fluid is placed at a height sufficient to obtain the desired degree of pressure. M. Sahli injects a pint of the solution every day, or even twice a day. Often copious diuresis results. In some cases the fluid is taken up and retained by the tissues deprived of their normal fluids by the disease process.

Copaiba Balsam as a Diuretic.

In the *Meditzinskoïe Obozreniïe*, Nos. 13 and 14, 1890, p. 73, Professor Ivan N. Obolensky, of Kharkov, warmly recommends copaiba balsam as a powerful diuretic eminently suitable for dispelling dropsies of cardiac origin. Having tried this old-fashioned remedy (in the daily dose of from 20 to 40 grains, in emulsion), in nine cases, the author has found that, 1. As a diuretic agent, copaiba is by far superior to digitalis, convallaria, adonis vernalis, stigmata maïdis and calomel. 2. It acts very quickly, an abundant diuresis being equally established about the end of the first 24 hours. 3. The effects are stable and long-lasting, the patient's organism showing no tendency to habituation towards the remedy (the same dose producing the same diuretic effects for weeks). 4. Of disagreeable concomitant effects, there are occasionally observed heart-burn with eructations, increased frequency of micturition, abdominal pain with liquid stools, and admixture of red blood-corpuscles to the urine. 5. Such phenomena, however, are always mild, no necessity arising to discontinue the administration of the remedy. 6. The balsam does not exercise any influence on the cardiac action, or pulse, or arterial tension. 7. Its diuretic action appears to depend upon its directly stimulating the renal secretory nerves.

Treatment of Hemeralopia with Injections of Antipyrin.

Hemeralopia is a condition in which vision is impaired so that it becomes imperfect when the light is not strong. Instillations of pilocarpine or eserine have been used in its treatment. The *Wiener medizinische Presse*, January 4, 1891, quotes three cases reported by Grandelément in *Lyon med.*, No. 50, 1890, in which good results were obtained by the subcutaneous injection of antipyrin on alternate days, for a long period.

THE

MEDICAL AND SURGICAL

REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

HEMATURIA IN TYPHOID FEVER.

Hematuria, or the passage of bloody urine, may arise from disease or from traumatism of the kidney, ureter, bladder or urethra. When from the kidney and ureter, the blood is usually intimately mixed with the urine; when from the bladder, the first urine passed is usually clearer than the last, and clotting is more common than in the case of hemorrhage from the kidney. When the blood comes from the urethra, it is possible, by passing a catheter into the bladder, to obtain clear urine. These statements regarding the characteristics of hemorrhage from the different urinary organs must, of course, be accepted as general truths only; exceptions are not infrequent.

A very rare cause of extra-renal hematuria is typhoid fever, and to it A. Létienne directs attention in a communication published in *La Médecine Moderne*, December 18, 1890. It appears from this paper that Chomel, Andral and Louis carefully noted in their autopsies on cases of typhoid fever the condition of the bladder. Subsequently J. Cossy, in 1843, collected their observations and published them, adding eight of his own. Following Cossy, Lecorché, Homolle, Murchison and Griesinger have all mentioned the condition and dwelt upon it with more or less detail.

The hematuria occurs frequently without premonitory symptoms, and without pain. In the cases observed by Létienne in the service of Lecorché, the blood was uncoagulated, and imperfectly mixed with the urine; the blood corpuscles were rapidly precipitated to the bottom of the vessel. There were no clots, or only small ones, indicating that there had been no notable extravasation in the bladder. The hematuria may not occur with each micturition; it may occur once, then disappear, to recur several days later, or it may be continuous. The quantity of blood varies in different cases.

Hematuria usually appears late in typhoid fever, though it may occur at the onset of the disease, as in a case reported by Lecorché. It has no such effect in reducing temperature as intestinal hemorrhage has; on the contrary, it may be followed by an elevation of temperature, for the lesion which causes it may permit of the re-absorption of septic products.

The prognosis of cases of typhoid fever in which hematuria occurs is generally graver, as the passage of blood indicates the wide dissemination of the infectious agent and a lessened resistance on the part of the patient. But, of course, if it constitutes the only anomalous symptom in a patient otherwise doing very well, it becomes of no importance. The lesions which provoke the hemorrhage appear in the form of ecchymoses, of nipple-like prominences, discrete or grouped ulcerations, and of gangrenous spots on the mucous membrane.

Hematuria occurring in typhoid fever is

admittedly rare, and some may think it not worthy of serious consideration. It sometimes happens, however, that the cause of a rare condition affords an explanation of some other condition not so rare and more important. It is well known that palsy follows many of the acute infectious diseases especially the exanthemata. Many cases are on record in which palsy has occurred during convalescence from typhoid fever, scarlatina and measles, not to mention diphtheria. The cause of these palsies has not been very satisfactorily determined. Doubtless hemorrhage occurs in a number of cases, the specific poison so acting upon the vessel walls that the blood can escape. This explanation is borne out and strengthened by the lesions just described as occurring in typhoid fever in the bladder, where they are so gross as to be capable of demonstration; whereas in the brain or cord they could be suspected only, since autopsies upon persons suffering with such palsies are rare and have been performed for the most part only after the palsy has lasted a long time and, consequently, the possibility of detecting the primary lesion very slight.

MATERNAL IMPRESSIONS.

The influence of maternal impressions upon the fetus in utero is a matter not only of scientific interest, but also of certain practical value. From the time of Hippocrates it has been held by the medical profession that psychical or physical impressions made upon the pregnant woman gave rise to marks, deformities and malformations evident in the child at birth. Such a view is also firmly implanted in the popular mind, as perpetuated in the term "mothers' marks." The problem is one difficult of solution. Though it may not be possible to explain the occurrence of abnormalities in the fetus as a result of influences acting upon the mother during pregnancy, the first step in that direction would be the collection and careful analysis of a large number of records of cases, so as to determine whether the association be merely accidental or coincident or related as cause and effect.

The *Edinburgh Medical Journal*, for January, 1891, contains an address read by Dr. J. W. Ballantyne before the Edinburgh Obstetrical Society, in which he reviews the subject of maternal impressions, and reports four cases. In one, a woman having an aversion to frogs was terrified early in her first pregnancy by a dead frog thrown at her by a friend. At term she gave birth to an anencephalic child. Becoming pregnant a second time she was again delivered of an anencephalic infant. The significance of this case is lessened by the fact that the father, by a first wife, had a hydrocephalic child. In the second case, a woman who was struck, during the third month of pregnancy, by a deaf-and-dumb peddler, gave birth to a child which at the age of three was yet deaf and dumb. In the third case, a mother gave birth to a child minus three fingers of the left hand: During her pregnancy, she had been alarmed by a wood-chopper falling heavily on the same three fingers of the left hand of another child. In the fourth case, one son resembled physically, mentally and personally a maternal uncle, while a second resembled the maternal grandmother. In each instance, the relative in question had been a source of anxiety during the respective pregnancy.

Dr. Parvin, in the second edition of his work on *Obstetrics*, also gives four cases of maternal impressions. To arrive at some definite conclusions upon this subject, it is recommended that the following points be inquired into: The period in pregnancy at which the impression was made; the character of the impression; the channels through which the impression was received; the mother was conscious of the impression and anticipated a defect in the child; the duration of the impression; the influence of heredity.

The practical deductions to be drawn

from this subject, independently of its explanation, are that during pregnancy a woman should lead a life of tranquillity, avoiding excitement, relieved of anxiety, spared depressing emotions and provided against deprivation and want.

DUST AND TUBERCLE BACILLI.

The question of the dissemination of tuberculosis is so interesting and important that we may call attention to an observation in this direction by Dr. M. T. Schnirer, of Vienna, recorded in the *Wiener Medizinische Presse*, January 4, 1891. One day in 1888, on rinsing the dust from some grapes, bought on a warm day, late in the summer, he found the water afterwards quite dirty. Struck by the thought of the large number of phthisical patients who eject their sputa upon the streets, he injected ten cubic centimeters of this water into the abdominal cavity of each of three guinea-pigs. One of the animals died in two days of peritonitis. The other two died in forty-five and fifty-eight days respectively. Examination of the bodies disclosed exquisite tuberculosis, originating at the site of inoculation, and partially caseous nodules in the peritoneum, in the liver, in the spleen, with but meagre deposits in the lungs. Tubercle bacilli were found in the nodules. Dr. Schnirer concludes that the conveyance was by means of the dust, as the water used was the pure spring water of Vienna, and the glass receptacle containing the water, the doctor's hands and the syringe with which the injection was made had been previously sterilized. He assumes, though without direct evidence, that the vender from whom the fruit was obtained was healthy.

The point Dr. Schnirer makes is, that tubercle bacilli may be in the dust of public streets, and may be attached to fruit or other articles exposed for sale and afterwards used for food.

This fear seems to be exaggerated and contrary to the inferences deducible from Cornet's investigations; for Cornet failed to find bacilli in street dust. Still, the observation of Schnirer is an interesting one, and its true significance may be estimated when taken in connection with facts continually accumulating. The experience of Schnirer may be open to inferences very different from those which he draws; but in any case, it is interesting to record and worth remembering in studying the important subject of tuberculosis.

DEATHS IN COLD WEATHER.

The recent cold weather in Europe serves to strongly illustrate the inability of the aged to withstand exposure. A recent number of the *London News* states that in the second week of December, 1890, the number of deaths among persons eighty years old reached 100, while during the following three weeks, which were so unprecedentedly cold, the number increased to 116, 142, 148. In persons afflicted with diseases of the throat and chest, the average was doubled.

While the fact that such severe weather is unusual there, and that people were not prepared to meet its rigors, accounts in a degree for the high rate of mortality, reference to the returns of our Philadelphia Board of Health shows that the rate here, where cold weather is not unusual, is decidedly higher in the colder months (in the months of January, February and March) than in the warmer months.

It is of the utmost importance that aged people expose themselves as little as possible during extremely cold or inclement weather, and when necessity compels them to do so, that they be well protected. No doubt if the increased dangers were sufficiently insisted on, in spite of the difficulty of making the average octogenarian realize that he is no longer young, the lives of many aged people would be greatly prolonged.

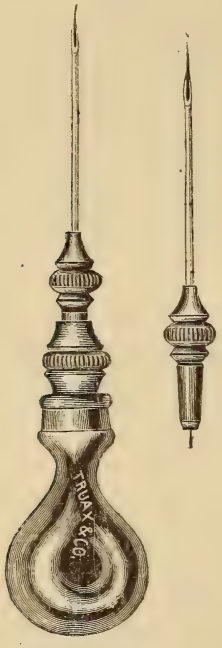
CORRESPONDENCE.

Aseptic Hypodermic Syringe.

To the Editor.

Sir: Will you kindly grant me space enough to add a few words more upon the subject of the aseptic hypodermic syringe devised by me.

In the issue of the Reporter for December 6, you print a wood-cut of the syringe of Prof. Koch, used in carrying out the treatment of tuberculosis. As you remark, the two instruments are constructed upon essentially the same principles, the exception being that the Koch instrument is much the more complicated of the two, with all that greater complication implies in increased liability to get out of order, greater expense, and difficulty of being kept in a strictly



aseptic condition. The graduated glass cylinder and the stop-cock features of the Koch syringe may have a use as yet unexplained in the carrying out of the Professor's ideas, but they are entirely superfluous in a syringe for all ordinary uses. In the admirable instrument made at my suggestion by Messrs. Chas. Truax & Co., of Chicago, and now for sale by that firm, the needle is connected directly to the bulb without the intervention of a glass cylinder. The directions for use are of the simplest sort. The bulb is pressed flat and the needle is inserted into some water. On releasing the bulb, the latter fills with water in five seconds or less. The water is discharged into a teaspoon, a solution is made of the tablet or powder, and the bulb is again drawn full, this time with the fluid ready for injection.

This system I have had in constant employment for nearly two years, using a roughly improvised instrument, but with never-failing satisfaction. The instrument maker now furnishes so perfect an article that a fair trial of its merits cannot fail quickly to place the bulb syringe well upon the way of superseding the ordinary form of instrument. The Koch instrument may have uses in carrying out the treatment at present associated with his name, but is not suited to ordinary everyday uses, and must be shorn of certain features before it can lay just claim to be an improvement in the direction of greater simplicity and increased efficiency.

Yours truly,

John J. Thomas, M. D.

Youngstown, Ohio.

Cancrum Oris or Gangrenous Stomatitis.

To the Editor.

Sir: On looking over the proceedings of the Tri-State—Alabama, Georgia and Tennessee—Medical Association, I noticed a report of a case of cancrum oris, which called to mind a similar case occurring in my practice in October 12, 1886. The patient, a white male, nine years old, lived eight miles in the country. I first saw the patient October 12. I made a diagnosis of typho-malarial fever. The temperature was high, the pulse rapid, the respiration hurried, and the tongue coated. The bowels had not moved for two days. The general condition of the patient, however, was good. I ordered hydrarg. chlor. mitis, gr. x; ipecacuannhæ, gr. ii; to be made into four powders, one to be given every three hours until the bowels were thoroughly moved. On October 13, at 10 A. M., the condition of the patient was much improved; the temperature was 102°, the pulse 110, the respirations 26. I now gave castor oil, and put the patient on quiniæ sulph., two grains every three hours, until ten grains were taken. I learned on the next morning that he had had several bilious actions during the previous night. I continued the quinine

for several days. Meanwhile all the symptoms seemed to have abated; when suddenly word came to me that the boy had grown worse. I saw him on the morning of October 21. His temperature was 104°; his pulse 130; his respirations 30; his bowels tympanitic, and he was very restless and complaining of severe pain in the left jaw. On examination I found a small, circular, red spot on the mucous membrane. I gave anodynes to relieve the intense pain, and used a solution of chlorate of potash locally. The symptoms continually grew worse, when, on October 24, the ulceration had grown to the size of a twenty-five cent coin, and extended through the whole integumentary surface, the lower molars becoming loose and dropping out; and the patient succumbed on October 26.

I report this case on account of its rarity, and to ascertain the possibility of its being cancrum oris, resulting from the fever or in any way the result of the mercury given in the beginning of the case. It is my opinion, and that of another physician whom I had in consultation, that it was a genuine case, otherwise mercurial salivation would necessarily have occurred, which did not obtain in this case.

Yours truly,

H. A. ALEXANDER, M. D.

Birmingham, Ala.

Politics and Pension Examiners.

TO THE EDITOR.

Sir: I wish to enter a vigorous protest against the sentiments expressed in an article copied in the REPORTER, February 21, 1891, from the *Indiana Medical Journal*, entitled "Politics and Pension Examiners." The article in question was undoubtedly written by some red-hot opponent of the administration, who takes this method of trying to create a prejudice in the minds of some members of our profession who do not take the trouble of posting themselves in regard to the workings of our system of government. The journal casts truth to one side as completely as the opponents of the administration did in the last campaign. No member of any Board of Pension Examiners is appointed by the President of the United States. The Commissioner of Pensions, with the approval of the Secretary of the Interior, makes all appointments of members of Boards of Pension Examiners. The President has nothing to do with these appointments. If Elbert has been appointed on the Board at Indianapolis, it was not the fault of President Harrison, and the author of the article in question should have known this fact before penning such a scandalous attack upon the man who fills the executive chair of this great nation with so much credit to himself and honor to the loyal people of these United States. The *Indiana Medical Journal* disclaims being a "partisan paper," but in the opinion of your correspondent, in this editorial it has descended to the lowest depths of bitter partisanship. It has not even kept within the limits of truth. And the Marion County Medical Society so far forgot its own dignity (if it passed the resolutions quoted) as to lend itself as an instrument to insult the President, and prostituted itself to base "partisan purposes" as completely as any rabid, ultra sore-headed convention of those opposed to the administration could have done. Politics is the Science of Government, and this science is one of the expressions of Truth. President Harrison has never appointed an "incompetent negro" to any position whatever. The Editor of the *Indiana Medical Journal* should stick to medical topics, instead of going into partisan politics, if he wishes to retain the respect of the medical profession outside of his narrow coterie in Indianapolis.

Yours truly,

R. L. MOORE, M. D.

Lincoln, Neb.

NOTES AND COMMENTS.

Benzin as an Antiseptic.

The *Cincinnati Lancet-Clinic*, February 7, 1891, contains an interesting article by Dr. F. W. Langdon on the use of benzin as an antiseptic and parasiticide. Dr. Langdon says:

The substance to which I desire to direct attention in the present communication is the ordinary commercial article, obtained in the distillation of petroleum, and employed in the arts as a cheap solvent of oily matters, paints, etc. Partly deodorized and re-named "rose-oil" it serves for removing grease spots from gloves and textile fabrics. It is known to the chemist as a hydro-carbon of varying constitution, and has, like all such bodies, a marked affinity for oxygen. It is often confounded (in ordinary reading)

with *benzole* or *benzene*, and I have, therefore, exhibited some of the more important contrasts of the two bodies in tabular form:

BENZIN OR BENZINE.	BENZOLE OR BENZENE.
Distilled from petroleum.	Distilled from coal-tar.
A mixture of hydro-carbons of the "marsh-gas series."	A hydro-carbon of the "aromatic series."
Specific gravity, .670-.675.	Specific gravity, .850.
Chemical formulæ: $\begin{cases} C_5 H_{12} \\ C_6 H_{14} \\ C_8 H_{16} \end{cases}$ etc., varying in exact constitution, but within definite limits.	Chemical formula: $C_6 H_4$ Unvarying in constitution.
Commonly used in dissolving oils and pigments, cleaning greasy machinery, textile fabrics, etc.	Used in dissolving gutta-percha, India-rubber, sulphur, phosphorus, iodine, some resins and alkaloids, and by microscopists for dissolving Canada balsam.

I use the above rather simple method of contrast in preference to tables bristling with the hieroglyphic diagrams of atomic constitution with which modern chemistry has familiarized our eyes, if not our understandings. It is the substance described in the first column of the table which forms the subject of the present paper.

Many years since, my attention was attracted to its value as a destroyer of low forms of animal and vegetable life, and when a boy it was my favorable application for the destruction of the larvæ of various parasitic insects (moths and beetles) known as "museum pests," as well as for the removal of molds and other vegetable parasites from bird-skins and insects.

In 1880, during my service as interne at the Cincinnati Hospital, and since then in private practice, it has fallen to my lot to treat a considerable number of cases of the skin disease known as *tinea versicolor*. It was the custom in the hospital to attack the fungus, which is the essential element in the disease, with various parasiticides, of which mercuric chloride was perhaps the favorite. This application (gr. iii to f℥i of water) effected an apparent cure for the time being, by destruction of the fungus on the surface, but invariably there would be a relapse in a few days or weeks—minute brownish spots re-appearing in the immediate vicinity of the hair-follicles and thence spreading and coalescing to form the characteristic pale-brownish patches, varying in size from a fraction of an inch to several inches in area. As it was evident that the relapses were due to the re-growth of spores situated in the depths of the hair follicles, where the watery solutions failed to penetrate, I was led to consider the advisability of using a more penetrating agent, and from my experience elsewhere in its use as a parasiticide, I selected benzin for experimentation.

Selecting a well-marked case, the application was made freely, twice a day, for three days, of a mixture of equal parts of common commercial benzin and tincture of green soap. This was applied by means of a small mop of absorbent cotton. At the same time, as a control experiment, a second case was treated with the bichloride solution. The result was that the growth disappeared in both cases, but the second case experienced the usual relapse within a week or ten days. The benzin mixture being now applied, a permanent cure resulted. I have since discarded the admixture of green soap as superfluous, sometimes diluting the benzin with a little tincture of lavender or other aromatic.

In numerous cases, in private practice, I have found it uniformly successful, not only in this disease, but in the skin diseases of mycotic origin generally, amongst which the ordinary furuncle or "boil" belongs. In the treatment of the latter important, if not dangerous affection, I have found benzin of marked value as an abortive agent, equal, at least, to the subcutaneous injection of carbolic acid, without even the small amount of pain and the slight danger of sloughing, attending the latter method.

The efficacy of benzin in furunculosis is easily demonstrated in that class of cases where one boil is followed, after its rupture, by numerous "seed boils," immediately surrounding its site, or by successive developments of single boils in the same region of the body. Here the prompt disinfection of the affected area, including the depths of the hair follicles, is a most certain method of arresting their progress towards suppuration.

The method of application is very simple. At the first appearance of the little, hard, painful papule, saturate a pledget of absorbent cotton with the remedy and press it firmly, but not forcibly, over the swelling, for about half a minute. Repeat this every hour or two for the first day, after that two or three times a day, as the swelling and pain subside. If suppuration has already taken place, in ever so small an amount, the only remedies, of course, are the knife

or spontaneous evacuation. Even with a small amount of pus in the original boil, its size may be limited and the formation of "seed boils" entirely prevented by the prompt use of the parasiticide. Due care should be taken to avoid the vicinity of a fire or light while making the application. No pain attends the application as above described.

Benzin is also the most useful and effective application for the destruction of the troublesome insects known as "jiggers" or chigoes, which, in many tropical, and some temperate countries, excite much pain and annoyance by burrowing into and laying their eggs in the skin. In the ordinary insect, as it occurs in our Southern States, and even in some parts of Ohio, I have found benzin the best remedy, penetrating their burrows and causing the death of the pests. The troublesome itching and irritation due to its movements are largely abated, though a red indurated area, surrounding its location in the tissue, will remain for some days.

Doubtless the remedy would give equally satisfactory results in scabies, but I have been unable to test it, for lack of clinical material.

I would also suggest its use in trichiniasis, as soon as possible after the ingestion of the infected meat, since a somewhat similar body, benzole (see table of contrasts), has been credited with good results in this disease. As much as two drachms has been given daily (of benzole) for from four to six days. In another recorded case, benzole was taken in quantity "of one or two ounces, probably," without dangerous symptoms. This would seem to indicate that its congener, benzin, in moderate doses, ʒss to ʒi, would be safe, and a remedy worth trying in this fearful and intractable disease.

Finally, the value of benzin as a solvent of oily secretions should not be forgotten in the preparation of skin areas for antiseptic operations. An agent that can penetrate and disinfect the pores and hair-follicles of the region to be operated upon, has advantages not possessed by any of the watery solutions in common use.

To summarize, we have in common commercial benzin an agent which is cheap, unirritating to the skin, not injuring or staining the finest fabrics, convenient of application, and possessing a wide range of usefulness as a parasiticide and anti-mycotic; its action being greatly aided by its solvent power over oily secretions, by reason of which the chief protection of the parasites is removed.

How it acts, I shall not attempt to explain, further than to note that its marked affinity for oxygen may be the key to its *modus operandi* as a parasiticide. Ignored by physicians generally, though found in every drug store at ten cents per gallon, and possessing a chemical ancestry (marsh-gas) identical with that of numerous remedies in common use, *e. g.*, ether, chloroform, iodoform, anilin, antifebrin, antipyrin, rhigolene, carbolic acid, etc., its non-use would seem to furnish another example of the truth of the adage, "Familiarity breeds contempt."

Sublimate Spray for Small-Pox Vesicles.

Dr. Talamon, in an article in the *Gazetta medica Lombarda*, 1890, of which an abstract appears in the *Journal of Cutaneous and Venereal Diseases*, February, 1891, says that, discouraged by the negative results which he had obtained in the treatment of small-pox patients with numerous internal medications which have been recommended and employed successively by a large number of physicians, he confined himself exclusively to the external and local treatment of the pustules. He tried spraying them with tannin, salol, iodoform and sublimate solutions. The use of internal remedies being, up to now, unable to cope with the germ of variola, he thought that by means of local antiseptics he might be capable of acting upon the microbes of suppuration, which cause destruction of the derma, and by a convenient modification of Lister's procedure abort the greater portion of the pustule by keeping its surface under the influence of an antiseptic.

The tannin sprayings were made with a solution containing one gram of tannin to ten grams of a mixture of equal parts of alcohol, ether and water. The tannin forms a varnish which compresses, flattens and drys the pustules, but at the same time it also produces a tension of the face of extreme painfulness, and analogous to that following the application of collodion. The use of a fifty per cent. ethereal solution of salol, sprayed on three or four times a day, calmed the pains, and was agreeable to the patient on account of the agreeable odor of the medicine. It was only found useful in the lighter forms of the disease. Its effects are nearly nothing in the coherent and confluent

forms, where the suppurative inflammation of the derma is more deeply situated. Iodoform as a fifty per cent. ethereal spray and used under the same conditions gave more satisfactory results than the salol, but less so than the use of the sublimate solution, but the disagreeable odor of iodoform rendered its employment offensive to the patient. The sublimate solution was prepared after the following formula:

Corrosive sublimate	1 gm.
Tartaric acid	1 gm.
Alcohol (90 per cent.)	5 c. cm.
Ether to make	50 c. cm.

This was applied as a spray three or four times daily; its use should not be continued too long, for it may produce a painful vesication in the form of long streaks. The individual's susceptibility to the irritant action of sublimate varies very much. In general a spraying of one minute is sufficient in skilled hands; the skin is seen to become whitish in color, which change also extends to the pustule. This coloration is due to a deposit of sublimate, and is the result which the procedure should yield. When, however, the skin is covered by pustules scattered with long interspaces, salol may be employed in order to prevent the action of sublimate upon the points not covered by pustules. Contact with sublimate is well tolerated; patients only complain of a sensation of heat, which is accompanied by a redness of the skin, more or less vivid. The writer has never observed any signs of mercurialism, which seems to indicate that the mercury is not absorbed, but only acts on the superficial layers of the derma. During the procedure it is necessary to take the precaution to protect the eyes by covering them by layers of cotton dipped into a saturated boric-acid solution. The application of the sublimate spray does not completely prevent the formation of pits, but they remarkably diminish in number and depth. It is best to commence on the first day of the eruption, after a vigorous washing of the face with soap, which may be rinsed off with boric acid and dried with absorbent cotton. If one commence on the third day of the eruption the use of soap will then be unnecessary. After the spray has been used the face should be covered with a layer of a fifty per cent. glycerolate of sublimate in order to keep the skin continuously antiseptic and free from outside germs. After the fourth day only two sprayings are necessary, but the glycerolate should be applied the same. At the end of the sixth or on the seventh day the use of the spray may be left off and the glycerolate used alone. As soon as the crusts separate the glycerolate may be substituted for the sublimate-spray, in connection with borated vaselin or salol. Dr. Talamon combined, in the coherent, confluent and grave forms of the disease, general sublimate-baths, prolonging their use for three-quarters of an hour to an hour; these, however, did not seem to have any well-marked action on the pustules situated upon the body. Still, those patients who were thus treated seemed to be less subject to the after-complications of convalescence so frequently seen. Finally, the buccal and pharyngeal eruption was treated by borated gargles and lotions.

This medication is absolutely powerless against the most severe forms—that is, the very confluent and hemorrhagic types.

Internally the therapy was limited to sustaining the strength of the patient by means of alcohol in doses of one hundred to two hundred and fifty grams daily, according to the gravity of the case. The quantity of alcohol to be consumed by the patient is increased by addition of water up to one litre; this mixture may be given continuously in broken doses.

Removal of the Gasserian Ganglion.

On Thursday, January 29, Mr. Rose operated for the removal of the Gasserian ganglion in the theatre of King's College Hospital. The patient was a female aged sixty, under the care of Dr. Ferrier, who had suffered for many years from severe neuralgia affecting chiefly the superior maxillary nerve on the right side. Chloroform was given, and after stitching the eyelids together on that side in order to avoid any accidental injury to the eye, a flap of skin was dissected forward, the zygoma was exposed, and, after openings had been drilled with an electro-motor, divided and drawn down with the masseter muscle. The coronoid process of the lower jaw was next drilled and divided in a similar manner, and turned up with the temporal muscle attached. The external pterygoid muscle was then cut through and the foramen ovale reached, into which the pin of a half-inch trephine was inserted, and a disc of bone surrounding it in this way removed. The bleeding was troublesome, and persisted for

some time. The ganglion was seized by some specially constructed hooks, one of which had a cutting edge upon its concave surface; by means of these its attachments were loosened and divided. Bi-chloride of mercury solution (1 in 3,000) was used during the operation. The bones which had been sawn were replaced and secured in position by wire sutures passed through the drill holes previously made, and a drainage-tube inserted. Cyanide gauze dressing was applied. The electric illuminator was found most useful during the deeper dissections. The patient has progressed most satisfactorily since the operation, having had no return of the neuralgic pain, although it is impossible to say at present that the whole of the ganglion was removed. The sutures were removed from the eyelids on the third day; the eye was healthy, but the conjunctiva insensitive. We hope to publish fuller details of this important case later. The operation which was witnessed by a large number of members of the profession and students, occupied about an hour and a half in its performance. We are glad to be able to state that the patient on whom Mr. Rose performed the first operation for the removal of the Gasserian ganglion in April last by a different method continues free from pain and is in good health.—*Lancet*, February 7, 1891.

Impure Drugs.

The *Medical Record*, January 31, 1891, says editorially: The last report of the New York State Board of Health shows that, while the sale of impure drugs is decreasing, it is yet lamentably large. During the year 1889, 807 samples of drugs were bought in the larger towns and cities of the State (excepting New York and Brooklyn) and subjected to analysis. The results are startling. Only 410 samples (50.8 per cent.) were up to the pharmacopœial standard, while 330 of the samples (40.8 per cent.) were totally deficient, by being either falsified, adulterated, decomposed, too strong, or too weak. The remaining 67 samples were of "fair quality." In some details the results of the analysis were as follows: Dilute acetic acid, 40 samples examined; 9 good, 6 fair, 19 inferior, and 6 of excessive strength; this is of unusual importance because of its use in the manufacture of spirits of Mindererus. Dilute nitric acid, 4 samples: 1 good, 3 excessive strength. Dilute sulphuric acid, 53 samples: 9 excessive strength. Hydrobromic acid, 38 samples: 6 inferior and 6 excessive strength. Saffron, 20 samples: 2 good, 1 fair, 17 inferior. Compound spirits of ether (Hoffman's anodyne), 47 samples: 4 good, 4 fair, and 39 inferior. Strong ether, 66 samples: 40 good, 4 fair, and 22 inferior. Precipitated sulphur, 25 samples: 6 good, 2 inferior, 17 inferior. Besides these, inferior samples of oxalate of cerium, chloral and chloroform were found. 115 samples of cream of tartar were bought at grocery stores, and of these only 30 were good preparations, 6 being fair, and 79 "clearly adulterated or falsified." Also there were examined 275 samples of alkaloidal preparations, including sulphate of quinine, citrate of iron and quinine, sulphate of morphine, and tincture of opium. Of these 177 were good, 13 of fair quality only, and 85, or 30 per cent., were "unreasonably deficient."

The object of the work is not so much to determine the proportion of adulterated to pure drugs on the market as to expose actual adulteration, sophistication and carelessness; to inform the public and to caution dealers. Consequently a great variety of drugs was not purchased, and only those were chosen that were likely to be adulterated. But though the frightful showing of the figures above does not represent the actual proportion of impure drugs sold, it shows the deplorable chance to which a physician in prescribing is subjected. One inclined to be facetious might remark, that, what with the difficulty of making a correct diagnosis, the furore and trouble the germs are creating, the chance of getting impure medicine, and the awful weather, it is a wonder that any of our patients live.

The practical value of these analyses comes from the fact that notices are sent to dealers from whom impure drugs are bought, notifying them of the impurities. Rarely does a second notice have to be sent and the standard of preparations is being gradually raised to that of the Pharmacopœia. The law is adequate to its purposes. It simply needs enforcement. After one or two or three warnings the penalties laid down should be applied. In the examination of alkaloidal preparations the bulk of attention was very properly paid to quinine preparations, as the report states that some druggists sell as many as two hundred thousand two-grain pills annually, and that fifty thousand is the estimate made of the

avarage number sold by a druggist doing an ordinary business.

Medical Society of the State of Pennsylvania.

The forty-first annual meeting of the Medical Society of the State of Pennsylvania will be held in Reading, on Tuesday, Wednesday, Thursday and Friday, June 2–5, 1891.

The appointments for 1891 are, 1. Address on Practice of Medicine, Dr. J. Chris. Lange, Pittsburgh; 2. Address on Surgery, Dr. O. H. Allis, Philadelphia; 3. Address on Obstetrics, Dr. J. Milton Duff, Pittsburgh; 4. Address on Mental Disorders, Dr. Samuel Ayres, Pittsburgh; 5. Address on Ophthalmology, Dr. J. A. Lippincott, Pittsburgh; 6. Address on Hygiene, Dr. A. B. Brumbaugh, Huntingdon.

The report of the Committee on the Revision of the Constitution, Dr. W. M. Welch, *Chairman*; and the report of the Committee on Incorporation, Dr. C. W. Dulles, *Chairman*, are to be acted upon.

The Chairman of Committee of Arrangements is Dr. Samuel L. Kurtz, Reading, to whom all applications to read papers at this session should be sent *not later than April 1*.

Secretaries of County Medical Societies are earnestly requested to forward at once complete lists of their officers and members, giving the post-office address of each.

Every delegate, before admission, shall present a certificate of delegation signed by the President or Secretary of his County Society.

Every permanent member (not a delegate), before admission, shall present a certificate of good standing in his County Society.

Railroad facilities will be announced when obtained. All who desire excursion orders should notify the Permanent Secretary, Dr. Wm. B. Atkinson, Philadelphia, stating what railroad must be used.

Warren Triennial Prize.

The Warren Triennial Prize was founded by the late Dr. J. Mason Warren in memory of his father, and his will provides that the accumulated interest of the fund shall be awarded every three years to the best dissertation, considered worthy of a premium, on some subject in physiology, surgery or pathological anatomy, the arbitrators being the physicians and surgeons of the Massachusetts General Hospital. The subject for competition for the year 1892 is On Some Special Subject in Physiology, Surgery or Pathology. Dissertations must be legibly written, and must be suitably bound so as to be easily handled. The name of the writer must be inclosed in a sealed envelope, on which must be written a motto corresponding with one on the accompanying dissertation. Any clew given by the dissertation, or any action on the part of the writer, which reveals his name before the award of the prize, will disqualify him from receiving the same. The amount of the prize for the year 1892 will be $500. In case no dissertation is considered sufficiently meritorious, no award will be made. A high value will be placed on original work.

Prevention of Narcotic Inebriety.

At a meeting of the American Association for the Cure of Inebriety, held Feb. 18, at the Academy of Medicine, New York, Dr. J. B. Mattison, of Brooklyn, offered the following preamble and resolutions:

Whereas, a leading cause of Morphinism, Chloralism and Cocainism is the facility with which morphine, chloral and cocaine can be procured from pharmacists: and,

Whereas, the refilling of prescriptions containing these drugs is a potent factor in the rise and growth of these diseases:

Therefore, be it resolved, as the sense of this Association, that no retail druggist should sell morphine, chloral or cocaine, except on a physician's prescription, and that no prescription containing morphine, chloral or cocaine should be refilled except on the written order of a physician.

These resolutions were unanimously adopted, and a committee consisting of Drs. Mattison, Crothers and Wright was appointed to secure legislation along the line of the resolutions.

Pyoktanin Stains.

Merck's *Bulletin* says that stains with pyoktanin may be removed from the hands by washing with spiritus saponatus, or with a ten per cent. solution of castile soap in alcohol, or with liquor sodæ chlorinatæ. Pyoktanin pencils, when broken, are mended by simply wetting the severed surfaces with water, and pressing them together gently; when dry they will cohere.

MEDICAL AND SURGICAL REPORTER,

P. O. Box 843, Philadelphia.

RELIEF FROM PAIN

AND

REFRESHING SLEEP

Can be obtained for your patient, by administering

℞ Bromidia (Battle) 1 ounce.
Papine (Battle) 1 ounce.

Mix. Sig:—One teaspoonful, repeated as required.

☞ The above formula is largely used by European and American physicians, and **UNIVERSALLY** gives entire satisfaction, **WHEN** the Genuine Products of the Laboratory of the well-known House of Battle & Co, are used.

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

Clinical Lecture.

JAUNDICE FOLLOWING THE PASSAGE OF BILIARY CALCULI.—JAUNDICE FROM ANGEIOCHOLITIS.[1]

BY WILLIAM PEPPER, M. D.,

PROVOST, AND PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE AND OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

Gentlemen: In anticipation of the discussion of hepatic disorders, which I shall make in a systematic way within a short time, I shall, to-day, call attention to some clinical illustrations of common affections of the liver.

This man, 60 years of age, was admitted to the hospital, October 28, four days ago. He has always been strong and healthy and temperate in his habits. He had syphilis 20 years ago, but did not have severe constitutional symptoms. For some years, he has had occasional pain in the region of the liver, but not marked enough to greatly inconvenience him. These pains were never followed by jaundice. His present illness began October 14, with severe pain in the pit of the stomach, where it remained fixed and was controlled only by the hypodermic use of morphia. Three days later he was found to be deeply jaundiced. Whether or not the jaundice began before this time cannot be stated. The pain continued for about four days. The bowels were costive at first, but since taking elaterium, they have been loose. There is tenderness in the epigastrium. The urine contained no albumin or casts and on October 31, it was amber clear. It is now more than two weeks since the attack, but yet he is still distinctly jaundiced. As you observe the skin of the entire body is yellow, although not deeply jaundiced. Probably, the best places to determine the existence of jaundice, so far as the skin is concerned, are about the chest, the epigastrium and the palms of the hands.

Let us now determine the cause of the jaundice in this patient, where I hope it may be readily arrived at. It is difficult to say how much importance is to be attached to these vague pains that have been mentioned as occurring more or less for some years. People often complain of pains about this region. They may have been rheumatic, but the last spell of pain was almost certainly dependent upon the passage of gall-stones. It is true that the pain was fixed at the epigastrium and that it did not extend up towards the right shoulder or through to the back, as the pain often does during the passage of gall-stones. It is, however, by no means constant that the pain of gall-stones extends in this way. It may be in the epigastrium, more commonly over the gall-bladder, and it may remain fixed in one place, although it is more common for it to extend upward and through to the back. I have repeatedly seen the pain connected with gall-stones referred to the epigastric region and remain there, as in this case. There is usually tenderness over the gall-bladder and about the position of the gall-duct. This tenderness may last for some time, as in the present case. It is readily explained by the irritation of the gall-ducts due to the passage of a rough or sharp-edged stone through the canal. Here are some specimens of average-sized gall-stones. Even one as small as the smallest of these with sharp edges, would set up inflammation of the gall-duct and account for the tenderness which we find. I call particular attention to this point as it has a bearing upon the diagnosis between gall-stones and simple catarrhal inflammation of the gall-duct. Very often at the time of the passage of the gall-stones there is vomiting.

[1] Delivered at the University Hospital.

But in this case, the man vomited only once and that was on the day following the severe pain. Usually, the bowels are constipated at the time and afterwards, and this is partly the effect of the pain and partly the effect of the sedatives given to relieve the pain, for usually powerful opiates are required, and these, of course, tend to produce constipation. The severe pain may last for an hour, or for several hours, or until it is controlled by an opiate. In fact, the pain may last for several days, as in this case. Immediately after the relief of the pain, jaundice is observed, or where the pain has continued for some time, jaundice may come on while the pain is still present. The pain sometimes stops abruptly, the little stone having forced its way through the duct and slipping into the duodenum; but you must not expect in all cases to find this abrupt ending of the pain. It often gradually subsides, but oftener the way in which it ends is masked by the fact that the patient has had a hypodermic injection of morphia or a suppository of opium or large doses of opium by the mouth, so that the way in which the pain ends is not known.

The jaundice is general. The mucous membranes and the skin are deeply stained. It is associated with the presence of biliary coloring matter in the urine. The movements of the bowels which follow the passage of a gall-stone are very light in color. Sometimes the stoppage is so brief that the bile enters the bowel again and mixes with the feces and there are no clay-colored stools. If the stoppage is longer, the feces will be pale. Often it happens, as in this case, that the patient has no opportunity to observe the character of the stools.

We note, then, as the symptoms of the passage of gall-stones, severe pain in the region of the liver, often extending to the shoulder and accompanied or followed by tenderness on pressure and usually vomiting. The pain comes on abruptly and may end abruptly, but often ends more gradually, or its disappearance is masked by the opiate. Jaundice comes on immediately after the pain, and sometimes while the pain is still present, if this lasts for a day or two. The attack is not attended with fever, but fever may follow as a result of the inflammation of the duct caused by the irritation of the gall-stone. The attack is usually not preceded by evidences of gastro-intestinal catarrh. There has not been a spell of diarrhœa or signs of gastric irritation. Of course, these may exist; but in the majority of cases they will not be found. This point is of importance in the diagnosis between gall-stone and catarrhal hepatitis with spasm. The only way in which the diagnosis of gall-stone can be positively verified is by searching the feces after the attack. The next or the two next stools should be secured, tepid water should be poured upon the fecal mass, which should be stirred with the whisk of a broom and then passed through a sieve, so that if any of these little stones are present they will be found. The failure to find gall-stones is not positive proof that there are none. The stone may have been broken up or disintegrated, or it may have become lodged in some pocket of the colon and not be discharged until some time after the attack. In the majority of cases, however, you will find it in the first or the second stool following the spell. The jaundice will last for a varying length of time according to the duration of the obstruction in the duct. If the stone has been large and has taken a long time to go through, the jaundice may last for ten days. If the stone has been small, the jaundice may pass away in a day or two. It also depends upon the amount of damage to the duct. If the duct is much irritated and inflamed and is swollen, jaundice may continue for several weeks, dependent not upon the gall-stone but upon the destructive inflammation of the gall-duct. This man has jaundice lasting rather long. It is now seventeen days since the attack and he is still jaundiced and there is distinct tenderness over the gall-duct. I take it that this is due to swelling of the mucous membrane partially closing the duct.

The diagnosis of gall-stone is usually easy. I do not know what it could be confounded with. Not with renal colic, for there the pain is in the back, running into the genitals with retraction of the testicle and frequent desire to pass urine. The urine is affected, often bloody and no jaundice follows. Sometimes gall-stones pass and no jaundice follows. I have not rarely noticed that—a sharp spell of pain and gall-stone found in the feces and yet no jaundice, because the stoppage was too short to permit resorption of enough bile to stain the skin, or because the stone was so small that there was not complete occlusion of the duct. In these cases you may be thrown off the track as the spells of pain may resemble gastralgia. I would advise you, therefore, if you have

paroxysmal pains that seem obscure, to have the feces carefully searched. I have found gall-stones even where there was no trace of jaundice. Sometimes I have secured as many as six or eight calculi.

I shall not to-day dwell upon the treatment of gall-stones. The most important part is prevention. Where you know that a gall-stone has been passed, you are anxious to prevent the formation of others. I wish to emphasize particularly the importance of getting the mucous membrane of the gall-bladder and duct in as healthy a state as possible. A gall-stone passing through the duct will injure and inflame it; thus a gall-stone may lead to inflammation of the duct; but on the other hand, inflammation of the duct may lead to the formation of gall-stones. The mucous membrane, being in a state of catarrh and more or less swollen, interferes with the free flow of bile, which remains in the gall-bladder, causing its distention, and thus the flow of bile is slow. The branches of the biliary duct have their lining thickened and there is a tendency for the bile throughout the liver to be retarded in its flow. This slow flowing bile becomes thick and there is a tendency to the deposition of the biliary salts or biliary coloring matter. As a result of the inflammation of the mucous membrane, little flakes or shreds of mucus are formed, and may constitute a nucleus which at once becomes encrusted with biliary salts and coloring matter, and we have the beginning of a calculus. I have no question that in many cases the formation of gall-stones is invited and favored by the presence of catarrhal inflammation of the lining membrane of the gall-bladder and duct. Therefore, in order to prevent the formation of other calculi, it is important to have the condition of the mucous membrane as nearly healthy as possible. For this reason I like continued counter-irritation over this region. In this case I shall apply a series of small blisters, an inch and a half in diameter, repeating them at intervals of six or seven days. The man will be kept quiet, with light diet and a mild saline to keep the bile free and thin. At the moment of the attack you have to relieve the intense pain. The best agents for this purpose are morphia and atropia hypodermically. Chlorodyne by the mouth is useful; but as there is sometimes vomiting it is not so prompt as the subcutaneous injection. Suppositories are too slow. Frequently one hypodermic injection of a quarter of a grain of morphia with a one-hundredth of a grain of atropia will lull the pain, and before the effect is over the stone has passed. If necessary, the injection can be repeated. If the attack is over soon, there is no seriousness about it. The patient should be kept quiet until the jaundice has passed away. Then preventive treatment, to relieve the irritation of the mucous membrane and to get the bile to flow freely, should be instituted. In the present case I shall give the man, in addition to a small amount of Rochelle salts morning and evening, a pill three times a day containing:

℞ Argenti nitratis . . . . . gr. $\frac{1}{4}$
Ex. opii
Ex. belladonnæ . . . . . āā gr. $\frac{1}{10}$

Jaundice from Angeiocholitis.

I shall now call attention to a young woman who came to me some weeks ago, and whom I sent here to watch her case carefully. She was induced to come because of the great improvement which followed in the case of a friend of hers, who came here with terrible jaundice, emaciated to a skeleton, and with a history of repeated spells of pain with deeper and deeper jaundice. The spells were also attended with fever and great soreness in the region of the gall-bladder. That woman was kept here for a long time. The diagnosis made was: obstructive inflammation of the gall-duct. We never found any calculi, although we searched for them frequently. I cannot assert that the gall-bladder is not full and practically obliterated, the pain having stopped because the stones are fixed. It may have been that the stones were too large to pass through the gall-duct; but one might enter and produce spasm and severe pain with jaundice, and then slip out. After remaining here some time, the woman got well and the skin became perfectly clear. In that case recovery took place because we cured the condition of the gall-duct.

This patient gives us the following history. She was admitted to the hospital two months ago. She has been married four years, and has had four miscarriages, but no living child. She was always healthy and could do the hardest kind of work until after her marriage at the age of 21. Within eighteen months after marriage she had three miscarriages, which she attributes to hard work. There is no history of venereal trouble. She has never had any symptoms, and her husband is said to be a strong and healthy man.

Two years ago last March she had her last miscarriage, which she attributes to cold taken during "the blizzard." She has not been well since. She had rheumatism four years ago and measles in February of this year. There is no family history of importance. The present illness began in March, 1888, with her last miscarriage. It began with a sense of distress in the hypochondriac region and between the shoulders. In June she began to vomit. Menstruation was scanty. She had a spell of vomiting lasting three days, and after that, every month from June to December she had an attack of vomiting for three or four days regularly at the time of menstruation. The vomiting partly took the place of the menstrual discharge, but not entirely. After December the periodic vomiting occurred every two weeks, and now menstruation stopped until April, 1889. Then she menstruated. It again stopped in June, and did not return until November. While she had the menses regularly the vomiting was less and occurred only at the monthly period. When the vomiting spells came close together and were severe, the menses disappeared. In June, 1890, she again missed the monthly sickness, which has not returned. She has vomited nearly every day during the past summer, mostly in the morning. She does not raise much, but has straining and gagging. Sometimes the matters vomited are coated with a little blood. In March, 1889, she began to have pain in the region of the liver, which has continued. It occurred over the gall-bladder and extended through the abdomen to the right shoulder. The jaundice has never left her. The skin is deeply stained all over the body. The urine is loaded with biliary coloring matter. She has had more or less diarrhœa since June, 1889, amounting to four or five movements a day, thin and of a whitish color. Her usual weight is 172 pounds, which is now reduced to 105 pounds.

Here then we have a history of periodic vomiting with marked evidences of intestinal catarrh, lasting since June, 1889, with severe jaundice beginning in March, 1889, and continuing until the present time. You will find nothing more difficult than to make an exact diagnosis in such cases as this. The points which strike one most forcibly are, in the first place, the protracted catarrhal irritation of the gastro-intestinal mucous membrane. I do not see how we can shut our eyes to that as the most prominent feature, where you have such a history. It is extremely probable that the inflammation has extended from the intestine to the bile-ducts, and caused catarrhal thickening and obstruction of these ducts and consequent jaundice. This we term catarrhal jaundice. The jaundice is the result of angeiocholitis or inflammation of the biliary vessels of the liver. I have already stated that you cannot assert that there are no gall-stones. In angeiocholitis the obstruction to the flow of the bile permits the formation of gall-stones, which may be shut up in the gall-bladder or may have come out from time to time. In this case we have not had any spells of pain indicating the passage of gall-stones. The woman has had continuous, not paroxysmal pain. For twenty months, she has had continuous pain in the region of the gall-bladder. There have also been cutting and knife-like pains at irregular intervals. The pain has never been severe enough to require the hypodermic use of morphia. There has been no great amount of fluctuation in the jaundice. She has been jaundiced continually. All of this points to the existence of some fixed lesion about the liver, and whether there be gall-stones mixed with it or not, it cannot be gall-stones only, unless it is a large gall-stone impacted somewhere. A large gall-stone entering the cystic duct between the gall-bladder and the hepatic duct and being impacted there could give rise to such symptoms as we have here. Usually, however, a gall-stone lodged in that position sets up inflammation and causes ulceration with fever, rigors and sweat. The ulceration advances until the patient dies from exaustion or the gall-stone passes by ulceration into the duodenum and the patient gets well. I have watched many cases where the stone has thus slowly advanced by ulceration until the cystic duct is obliterated, and the stone enters the common duct and this is obliterated, and it passes into the duodenum, with the recovery of the patient and the finding of a large stone in the feces. A large stone in the cystic duct which has not set up inflammation might account for the symptoms. There has not been much fever in this case. Lately there has been a temperature of 101°; but the course of the case has not been marked by much fever.

Turning now to a physicial examination of the abdomen, I find that the edge of the liver extends three inches below the margin of the ribs, showing that the organ is greatly enlarged. The surface of the liver is quite

smooth, the edge is thin and sharp and at most the surface is slightly granular. There are no tumors. I tried to find the gall-bladder, but cannot discover it.

What I suppose has happened here is that this woman, broken down by hard work and repeated miscarriages, the nature of which we do not know, had a violent gastro-intestinal catarrh and the inflammation has extended into the bile-ducts and set up angeiocholitis with obstruction, preventing the escape of the bile. This obstruction has been almost complete. Then the inflammation has extended from the mucous lining of the gall-duct to the peri-vascular connective tissue, setting up that type of cirrhosis which is known as peri-vascular or hypertropic cirrhosis. Around these dilated and chronically inflamed ducts we have thickening of the tissue of the liver.

The liver is uniformly enlarged. There is no reason here to do a laparotomy. One of the points that we have to settle in reference to a case of this kind is whether or not there is an impacted stone which should be removed with the knife. We have decided against laparotomy because the evidences of stone are not great enough ; while the evidence that it is a case of this type of cirrhosis with chronic inflammation of the gall-duct is very strong. If that is the case, I cannot help thinking that this woman should get well.

I need not say that the question of cancer comes up in every case of this kind. I think the fact that the disease has lasted so long, and the fact that there is no distinct mass and that there is more or less fever, with the youth of the patient, would serve to exclude malignant disease. In older people it often is a difficult question to set cancer aside.

Crystal Coating for Wood or Paper.—Mix a very concentrated cold solution of salt with dextrin and lay the thinnest coating of the fluid on the surface to be covered by means of a broad, soft brush. After drying, the surface has a beautiful mother-of-pearl coating, which, in consequence of the dextrin, adheres firmly to paper and wood. The coating may be made adhesive to glass by doing it over with an alcoholic shellac solution. The following salts are mentioned as adapted to produce the most beautiful crystalline coating—*viz.*, sulphate of magnesia, acetate of soda and sulphate of tin.

Communications.

A VIEW OF KOCH'S REMEDY FOR TUBERCULOSIS.[1]

BY WILLIAM HUNT, M. D.,
SURGEON TO THE PENNSYLVANIA HOSPITAL.

It is now time for me to speak briefly of the great medical event of the past year, which has attracted the attention and the hopes of the world at large, as well as of the profession of medicine and surgery.

Singularly enough, in January, 1883, it fell to my lot to give the annual oration before the Philadelphia Academy of Surgery. In that oration, the orator is expected also to notice what has occurred of interest to surgery during the preceding year. Koch announced his discovery of the bacillus tuberculosis in 1882, and that it was the cause of consumption and other tuberculous diseases. The announcement attracted as great professional interest as the one of 1890; but of course it did not create such a public *furore* as this one, because naturally the public are not interested to any extent in the *science* of medicine, but they are intensely interested in the cure of disease. It was a notable occasion in 1883, because we had, besides the oration, a microscopic exhibition of micro-organisms, among which were two or three slides (I think obtained by Dr. Formad) containing the bacillus tuberculosis. These were the first seen in this city and among the first in the country, and, of course, attracted much attention.

Now it becomes my duty to notice the startling announcement of the same indefatigable bacteriologist, that he has discovered a method of destroying tuberculosis tissue *in situ* and of thus preventing the ravages of the most potent enemy of human life known to mankind. Is it any wonder that such an announcement was received with profound astonishment, and on the part of all with the most respectful, and, I might say, with the most reverential regard? Berlin was the centre of attraction, Koch the object of honor. We all know how the representatives of science and the victims of sickness flocked to that city.

It is unnecessary for me to go over the

[1] Portion of an address delivered at the last annual meeting of the Association of Ex-Residents of the Pennsylvania Hospital.

history in detail, as it is familiar to all. The efforts at secrecy, the general and professional condemnation of this course, the revealing of the composition of the remedy, the spare granting of small quantities of it to certain favored ones and the distribution to different parts of the world of the precious liquid are equally well known.

And, with it all, no disrespect, no denunciation or no ridicule of the famed discoverer. His behavior throughout has been grand. He never wished for publicity, but was forced, as it were, by popular and professional clamor into exposure. Time, much more time, was required for laboratory and test work.

When, then, he announced, "The remedy, therefore, is a glycerine extract of pure cultivations of tubercle bacilli," he made no boastful claim, but told us how and when to use it, and of its dangers as well as of its benefits. Is its use to end in bitter disappointment or not? Koch, himself, must have been as interested as any one in that remarkable lecture—we might say clinical lecture—of Virchow's, held the 7th of January, 1891, when he discussed Fraenkel's paper at the Berlin Medical Society. I do not think Koch was present. The scene must have been very impressive. The veteran and profound pathologist stood at his table, and on it were what was worth showing, from *twenty-one post-mortem* examinations of patients who had died after the injection treatment. Think of this at one clinic! Of the twenty-one, 16 were cases of pulmonary phthisis. These were the cases to the end of December. The lecturer speaks of 6 or 7 cases in the present year up to January 7, and he says, "in addition to this my assistants have made necropsies in a large number of similar cases at other hospitals and in private, and I have seen the most important results of the examinations." The crowded audience gazed with intense and silent interest, as he took up piece after piece and showed the changes that he thought were due to the old disease and those that were brought on by the new treatment. No word of disapproval or ridicule escaped him. The specimens themselves proclaimed their own lessons. A mere superficial notice of what was shown and said at that lecture can only be made here. You may have read it, or if not, you can read it in the *British Medical Journal*, of January 17. He showed extra hyperemias in a case of tubercular arachnitis, and evidently thinks that the fatal result was precipitated by the remedy.

Again he says, "In particular it was repeatedly noted by us, that even the surfaces of pulmonary cavities showed unusually intense redness of the granulation layers; moreover *hemorrhagic* infiltrations of the walls were not seldom present, and even recent hemorrhages were observed in the cavities."

After describing certain swellings, rapid proliferations, etc., he says: "These swellings occasionally assume a very dangerous character. I will only refer to the phenomena which are seen in the larynx, where even in cases where the ulcerated surfaces become clean, the adjoining parts swell to an enormous extent and cause constrictions of a very critical nature. Together with these changes there occasionally occur other more violent forms which take on a phlegmonous character and remind one of œdema glottidis erysipelatodes, and retro-pharyngeal abcess"—and here he showed specimens.

Again: It was noticed that among the fatal cases of ulcerative phthisis that the large majority exhibited recent changes of great extent, more particularly in the lungs, but also pleurisy and for the most part very severe pleurisy, simple and tuberculous, frequently hemorrhagic, and not infrequently bi-lateral. He then, with the fairness of a fair-minded man, discusses whether the lesions exhibited were due to the treatment, or would have occurred in the natural progress of the disease. Showing a specimen he says, "From the most characteristic of one of these comes this piece of lung, which shows such extensive caseous hepatization that I do not remember to have seen anything like it for years." And then, most important of all, he discusses the development of *fresh* tubercules in these cases, and gives by observations strong proofs of their happening, and says: "I am strongly convinced that these fresh eruptions first appeared *ex-post*." He speaks of the mobilizing of bacilli and setting them free to attack other parts, and gives a characteristic example. The breaths of the audience must have almost stopped at the end of this lecture.

After reading it at the library of the College of Physicians, I was involuntarily reminded of the drawings we have in the Mütter Museum, taken from Dr. Weir Mitchell's cases, and showing the effects of rattlesnake bites on pigeons. Man often is a stupid

animal. He knew the anatomy and action of the rattlesnake hypodermic, years before he invented a little machine for his own professional use. This dreadful Virchow lecture shows that now he can compete with the snake for results.

Hear the other side! Is there one to hear? Has a favorable report been given anywhere in the world to offset this one of Virchow's? I can find reports of none, and I have looked over many reports. Every clinician is in waiting. The editorial in the same journal that publishes the report of this clinic is very fair. It says: "That these observations are of enormous value; that any one who thinks that all that is necessary to practice Koch's method is to have a bottle of the lymph and a hypodermic syringe, is mistaken; that he who thinks of carrying it out should make himself thorough master of Koch's original statements, which are calm to a degree and are as unbiassed as any man could expect those of the author of such a method to be. The method is still on trial and those who wish to keep an open mind can do so only by a careful study of scientifically observed facts as they are placed before us."

And so say we all of us—Wait! That the present dangers are recognized through the influence of Virchow's clinic, is shown by this telegram in our papers dated Feb. 13—only four days ago—"An important discovery. Dr. Weyl, an associate of Professor Koch, has discovered a method of detecting in the Koch lymph the poisonous elements described by Professor Virchow, and of eliminating them so as to produce a lymph free from bad properties."

There is nothing new. That charming and learned writer, Benjamin Ward Richardson, has a short article in the last number of the *Asclepiad*, on Pulmonary Consumption, which opens thus: "In many parts of provincial England it was once a practice, hardly yet abolished everywhere by the common people, to treat persons affected with consumption of the lungs by making them swallow live snails. The vulgar idea of the *modus operandi* of the medicine was that the snails found their way to the lungs of the patient and ate the black worms which lived on the lungs and caused, by their depredations, the disease. The snail treatment got a great reputation, for which probably it depended on two collateral causes. The persons who were benefited by it were led to seek the remedy in purer air than they had been accustomed to live in; and in addition to the snail, which did neither good nor ill, they partook freely of new milk and cream, rich foods likely to be important adjuncts in the cure. Of late the idea that pulmonary consumption is a parasitic disease is revived. The lungs infested with hosts of a specific bacillus is supposed to be destroyed by them or by the secretion which they eliminate; and the mode of cure is expected to be found in a lymph or poison which shall kill the bacillus without injury to the patient." Further on the writer shows that he keeps his opinions in reserve for he says: "But scientific medicine is conservative and careful before she speaks a word; and the more so because, in her too ready acceptance of speculative practice in former days, she has reason to become wary and chary of belief. Some of her children run after new remedies and false gods fast enough; and many, no doubt, will run after this new promise long before there is sufficient evidence either for its establishment or its delegation to the shades of departed fallacies."

Again we say, Wait!

VERATRUM VIRIDE.[1]

BY AARON C. WARD, M. D.,
NEWARK, N. J.

A careful study of the pathology of pneumonia not only leads to the conclusion that bleeding does harm, but that the use of all those agents which have been employed for the arrest of simple pulmonary inflammation are contra-indicated strongly. Hence veratrum viride, aconite, antimony, calomel, and all so-called "cardiac sedatives" have been discarded, for it is evident that they add a new load to an already over-burdened heart. They may for a time lower temperature and pulse rate, but this will be accomplished at the expense of heart power. "Cardiac insufficiency will therefore appear earlier and be more profound;" so says Prof. Loomis, and the principle expressed in this statement underlies the practice and teaching of a large class of intelligent physicians, whom we are wont to look upon as authorities.

That what seems to us an error should have such a strong foothold is the excuse for this brief essay. I believe the above position

[1] Read before the Practitioners' Club.

is untenable, and the arguments used in its support unsound physiologically and physically. For, first, the circulatory activity which occurs in pneumonia is not compensatory; that is, it is in no way dependent upon or proportionate to the obstruction existing in the lung or the consequent diminution of respiratory area. This is demonstrated by the fact that in all cases the cardiac activity is in excess of the amount necessary to compensate for the defective respiration; by the fact that we find just as high arterial tension and just as rapid heart-action when one lobe is involved as when two are; and, again, by the fact that the same condition of the circulation exists in other inflammatory affections where the respiratory surface is neither diminished nor its functional activity impaired.

In the second place, the amount of compensation which is rendered necessary is largely accomplished by the increased rapidity of the respiratory acts; while it would not be difficult for the respiratory apparatus, under favorable circumstances, to compensate entirely for its own defect without making any extra demand upon the heart. Moreover, such a result is eminently desirable, for the muscular apparatus of respiration can better bear over-taxation than can the heart.

In the third place, suppose that heart failure in pneumonia is principally the result of the effort of the heart to overcome the increased resistance in the lung, even so the auxiliary proposition is untenable—namely, that cardiac depressants increase, while stimulants decrease, the burden thrown upon the heart and the venous stasis which results. The converse proposition is much more rational and more in accordance with the facts. For though it is likely that arterial tension alone is not sufficient to produce exudation in an otherwise normal circulatory apparatus, yet it is certain that from the instant exudation is rendered possible by pathological changes in the walls of the vessels, the higher the arterial tension, the more rapidly the exudation takes place, and therefore the greater will be the severity and extent of the local inflammatory process. Again, if we consider the circulation as a whole we will see that the blood must complete the circuit of the pulmonary capillaries in the same space of time that it traverses that of the systemic capillaries. It follows that, whatever the pressure, if we could introduce an obstruction to the flow of the blood through a part of either system, the circulation in the remaining normal part of that system would of necessity be more active; in other words, there would occur in the rest of that system a compensatory or active hyperemia. Under such circumstances, any pathological condition which would increase the rapidity of the general circulation would proportionately intensify the embarrassment of the defective system, and *vice versâ*.

Again, the amount of energy necessary to be expended in injecting a given amount of fluid into an elastic reservoir is proportionate to the tension already existing in such reservoir.

Now the tension of the systemic circulation is normally at least five times greater than that of the pulmonary circulation. Therefore, to overcome any given increase in the systemic arterial tension requires the expenditure of five times as much of the heart's energy as a corresponding increase of tension in the pulmonary circulation; or, in other words, it would not be difficult to prove that the labor thrown upon the heart by the increased arterial tension of the systemic vessels which exists in pneumonia, is greater than that which would be caused by the total obliteration of the circulation through a whole lobe of the lung. Under such conditions it follows that we can do as much to save the heart from exhaustion by lowering the arterial tension of the system at large as we could were it possible for us to remove entirely pathological resistance existing in the diseased lung.

Again, the rise of temperature which occurs is proportionate to the circulatory activity, and is produced by the excessive oxidization and tissue waste which such abnormal circulatory activity makes possible. "No argument is necessary to convince you that the vital powers are rapidly exhausted when the heart is driving the blood through the system at the rate of 120 or 140 beats in a minute." Could anything be more irrational than to allow the heart to waste its own energy in destroying the energy of the system at large, and content ourselves with alleviating one of the injurious results of this process when it is within our power to remove the cause?

Again, we find the same physicians who so strenuously oppose the use of veratrum in pneumonia, in the next breath recommending other agents, whose value, where any such exist, rests upon the same basis as that

of the veratrum they discard. Or we find them using this same veratrum in other affections, in which practically the same conditions exist, and the same therapeutic indications are to be met as in pneumonia. For example, Niemeyer says in favor of the "bath" in pneumonia: "the temperature declines, and pulse falls and becomes soft and compressible, the skin grows moist and the patient feels refreshed," and this same authority, to use his own words, "feels it necessary to emphasize the evil effect of cardiac sedatives" administered in this disease. Or, again, how do those who contend that veratrum is inadvisable in pneumonia because it augments venous stasis and increases the labor of the heart, explain their endorsement of its use in the hypertrophy of the heart of chronic Bright's, where, practically, the same circulatory conditions exist?

Finally, we meet in practice several classes of cases such as chronic interstitial pneumonia, etc., where, as far as the lung is concerned, the circulatory conditions are identical with those in pneumonia, and yet in these cases there is no embarrassment of the heart, no compensatory hypertrophy, and no venous stasis, even though the disease has existed for years. Could any evidence be more conclusive?

If the foregoing reasoning is sound, I think I have proved that the rational treatment of the first stage of pneumonia is to reduce arterial tension, as far as that is possible consistently with the performance of those functions for which the circulation exists, namely, the distribution of nourishment and oxygen and the elimination of waste products. The degree of circulatory activity which may be necessary to attain these ends may be greatly reduced, on the one hand by supplying the nourishment and oxygen in such a form and degree of concentration as shall render assimilation more easy and rapid, and on the other hand by assisting in the many ways at our disposal the activity of the other emunctories, that their increased functional activity may compensate for the impaired elimination through the lungs.

In the foregoing argument we have spoken of pneumonia, because it is more easy to treat anything in the concrete than in the abstract, and also because pneumonia furnishes one of the most important applications of the principles involved. The conclusions at which we have arrived in the case of pneumonia are equally applicable to almost any other acute inflammatory process accompanied by high arterial tension; for example, pharyngitis, tonsillitis, laryngitis, bronchitis, bronchial pneumonia, pleuritis, peritonitis, nephritis, etc. To accomplish the desired sedative effect upon the circulation, our professional ancestors had resource to venesection, and though this occasionally proved of great service, yet, unfortunately, it involved an absolute loss of vital power, which experience has gradually taught us overbalanced the advantages to be gained. The practice has therefore fallen into disuse.

I shall not, however, consume your time in attempting by comparisons to demonstrate a proposition which, it seems to me, is beyond question, namely, that veratrum viride is the most rapid and most efficient cardiac sedative we possess; but I will turn immediately to the consideration of the other objection raised by its opponents, namely, that its sedative effects are obtained at the expense of heart power.

Any discussion of the physiological action of the several alkaloids present in this drug is foreign to our subject. Suffice it to say, that its physiological action as a whole is due to the combined effects of at least three distinct alkaloids, individual actions of which differ mainly in degree.

The important and characteristic actions of veratrum viride can all be considered under the two main heads; its effect on muscular activity and its effect upon the nervous system. Veratrum diminishes muscular excitability. This is an important fact, for while the sympathy of the motor nerves in this action is not completely disproved, yet it is demonstrated beyond a doubt that the action of veratrum viride mainly affects the muscles, and that its influence on the motor nerves is comparatively subordinate. A muscle so poisoned reacts for a long time to direct or indirect irritation, but this action is different from that which occurs in its natural condition. For while the contraction is performed in the ordinary time, the relaxation is very much protracted.

Veratrum exerts little or no influence on the motor and sensory nerves and upon the cerebral centres. To this statement there are several exceptions: the vasomotor centre is powerfully depressed; the activity of the pneumogastric is stimulated; the reflex of the spinal cord is at first markedly diminished and finally abolished; while the effect on the respiratory centre is in doubt. Whether or not this centre is affected, it fol-

lows from what has already been said in regard to muscular activity, that respiration must be slowed and finally cease. In the case of the heart, the same reason holds good, but here another factor enters the problem. The pneumogastric being more rapidly affected than muscular activity, the heart's action is at first slow, without the force of the individual beats being much altered. Later, when the muscular tissue of the heart feels its influence, the force also is lessened. Larger amounts of the poison finally produce paralysis of the terminals of the pneumogastric and of the cardiac muscle. The ultimate effect, therefore, on the heart is complete paralysis.

In consequence of the powerful depressing influence upon the vasomotor centres and the diminished force and frequency of the heart's action, arterial pressure is progressively and rapidly diminished. The free perspiration which occurs is another result of the vasomotor depression. The pulse, under the combined influences on the circulation, is at first slow and full, though always soft and compressible; later its strength is diminished, the rapidity being at the same time even further reduced.

The symptoms of a poisonous or excessive dose are simply an exaggeration of the physiological effects, and are almost precisely like those produced by tobacco in persons unaccustomed to its use. Intense nausea; incessant and violent vomiting and retching; complete muscular prostration with attacks of dizziness or fainting; slow and superficial respiration; a small, feeble and sometimes almost imperceptible pulse; an expression of great anxiety; a cold, clammy skin—these and associate symptoms present a condition which is at once distressing and alarming.

The rapidity with which the effects of veratrum viride disappear when its administration is suspended, and the almost entire absence of any persistent derangement of the functions affected, have been matters of general observation. They follow naturally as the result of the *modus operandi* of the drug and the rapidity of its excretion. The importance of their practical bearing is apparent. For if the physiological action of veratrum, as given above, is correct, it refutes the second objection raised by our opponents, and, on the contrary, warrants the assertion that veratrum is a heart tonic in the broadest sense of that word. This error probably arose because, while observing phenomena, the fact was lost sight of that there is a real and positive distinction between a weak pulse of repressed energy and that which results from absolute loss of power.

Just here it is proper to state, and to emphasize the statement, that while veratrum will absolutely and invariably control the quick, hard pulse of inflammation, it just as certainly will *not* reduce a feeble, rapid pulse of exhaustion, and this for the very simple reason that you cannot conserve energy which does not exist. Failure to recognize this distinction probably accounts for many of its reported failures.

The next question naturally presents itself: Is not the administration of such a drug so hazardous as to render its general use undesirable? This I answer in the negative, without any hesitation or qualification. While there are on record numerous cases where the alarming condition of the patient gave reason to expect a fatal result, yet in almost every instance we find that complete recovery has ensued. The number of fatal cases is small. On the other hand, the testimony of those who have given veratrum the most thorough trial and whose ability to judge is beyond question, is unanimous to the effect that there is practically no danger attending its use—absolutely none when intelligently administered.

Referring to the unpleasant symptoms resulting from an overdose, Barker says: "After an experience of more than thirty years in the use of veratrum, I feel warranted in saying that these phenomena are really not dangerous. I have never known any serious result to follow from its use. This condition is purely temporary, and patients pass out of it in a short time, even if no restoratives be given."

Wood affirms that, "although veratrum viride is a remedy of great power, capable of producing the most alarming symptoms, yet I believe it to be the safest of all cardiac depressants; certainly it is far less dangerous than aconite. It is somewhat doubtful whether a robust adult could be killed by a single dose of any of its preparations, especially if prompt and judicious treatment were afforded."

The evidence adduced is surely sufficient to establish the assertion that its intelligent administration is devoid of danger. It is no argument against a drug that it is capable of doing mischief, if, when intelligently and judiciously administered, its therapeutic value

is available without incurring the risk of such mischief. To advance such an argument is to plead ignorance or indolence.

The therapeutist has at hand numerous drugs which, if not more powerful than veratrum viride, are yet more singly spinal depressants. The field of its usefulness in this direction is therefore limited. I hope to show, however, that there is one condition in which its composite therapeutic effect renders veratrum the most valuable spinal depressant at our disposal.

However widely authorities may differ in their theories as to the exact pathology of puerperal convulsions, or in the remedies that they may advocate for the treatment of the same, there is practical unanimity as to the therapeutic indications to be met. Briefly these are, to lower arterial tension, to diminish to the fullest extent practicable the irritation of the vaso-motor and convulsive centres, and to restore to the kidneys their normal function. Venesection meets the first indication perfectly, by rapid reduction of the volume of the blood. It meets the second indication, though partially only, by removing a part of the toxic ingredients from the circulation, and by both these means it relieves somewhat the renal embarrassment. The testimony as to the prompt relief afforded is overwhelming, and this not only by those who wrote at the time when venesection was the orthodox treatment, but to-day, when in the face of public sentiment we find such men as Barker, Lusk and others pleading for the restoration of the lancet, and insisting upon the unmistakable clinical evidence in its favor. All admit, however, that because the arterial tension is rapidly re-established and the remedy cannot be repeated, the relief afforded is only transient, while the deterioration of the blood which ensues cannot but increase the danger of the disease. Its employment, therefore, is justifiable only in a most pressing emergency, on account of the rapidity of the relief afforded, and as an expedient to gain time for the action of other more satisfactory measures.

I have considered venesection to such length, principally because its success confirms a point which I desire to make, namely, that the reduction of arterial tension alone is sufficient to afford relief in this most distressing malady. The other agents most generally employed to-day are chloroform, chloral, potassium bromide and morphia. These are dependent for their usefulness on their antispasmodic power, since in the quantity which can be administered with safety they either do not at all influence arterial pressure, or they exert an unfavorable influence by raising it. They are not without merit, but as in each case this is qualified or offset by some danger or unfortunate concomitant action, their employment should, we think, be secondary and supplementary to the use of that remedy which theoretically and practically fulfils all the indications more perfectly than any single agent in the pharmacopœia. This remedy is veratrum. For veratrum is both the most powerful of arterial and of spinal depressants, and, at the same time, exerts a specific depressing effect upon muscular tissue in general. In other words, veratrum is not only a central antispasmodic, but a peripheral antispasmodic as well; if I may be allowed to use such an expression. Its action, moreover, is rapid and can be maintained almost indefinitely without danger. As regards the dosage in this condition, all that can be said is that enough must be given to bring the pulse down to about 60, and its administration must be continued for some time afterwards, and in such smaller doses as shall be sufficient to keep the pulse at about this rate. In order to save time, the initial dose at least is best given hypodermically.

In conclusion, I will cite briefly three cases to illustrate in practice the principles for which we are contending.

Case 1. Mrs. H., 45 years old, strong, well-nourished, previously well, was seized with a severe chill, followed by rapid rise of fever and pain in the side. I was called six hours later. The patient's face was flushed; pulse, 116, full and strong; temperature, 104°; stitch-pain in right side; frequent, restrained painful cough; pain intensified by full inspiration; respiration, 28. There were physical signs of pneumonia in the first stage, affecting the lower lobe of the right lung. I gave calomel (gr. x), sod. bicarb. (gr. xx), and tincture of veratrum viride (♏ iii), followed in half an hour by ♏ ii, and afterwards ♏ ii each hour. Counter-irritation was employed, etc. After the third dose of veratrum the pulse was 56; temperature, 102°; slight nausea; pulse maintained below 60 or 65 for two or three days. The physical signs persisted, increasing very slowly. The patient recovered, without having had consolidation of the lungs, in about the usual time. The inflammation seems in this case to have been held in check, the

lung never getting beyond the stage of intense congestion.

Case 2. A strong, healthy boy, 10 years old, had a severe chill with fever, cough, dyspnœa, etc. Six hours later his temperature was 103°, pulse about 140, respiration about 70. There was great dyspnœa; the skin was somewhat cyanotic; the cough was frequent and distressing, without expectoration. Prostration was great. There were physical signs of intense congestion of the lungs; the patient was apparently dying. Veratrum was given in frequently repeated small doses until the boy was nauseated. After three hours I saw the patient again; he was quiet, dyspnœa was relieved, the skin was more natural in color, the pulse below 90, and the respiration about 40, the temperature being 102°. The pulse was kept between 80 and 90, and recovery was rapid.

It does not follow that veratrum viride is to be discontinued after the first stage of pneumonia. While I am opposed to the custom of giving stimulants, saline or alcoholic, as a routine practice, yet I am perfectly willing to admit that, from this point on, their use in greater or less quantity is called for in a large proportion of cases. If at the same time we stimulate, however, we can so regulate the energy evoked that it shall be utilized with the least possible waste, we are doubly at an advantage. This we can accomplish by giving small doses of veratrum viride, along with a proper amount of alcoholic stimulant. For you will remember that the primary effect of veratrum is to decrease the rapidity of the pulse without affecting materially its quality. This primary effect can be maintained if the dosage is properly regulated. The administration of veratrum is not at all incompatible with the use of alcoholics, as is apparent in the following case, cited by Dr. Barker: "Veratrum viride alone did not seem to produce any effect on this case, the pulse remaining constantly above 130. It was decided to give brandy. After the first ounce had been given the pulse fell to 108; after the second to 86. Continuing the brandy, the veratrum viride was suspended for a few hours. The pulse again arose to 130. After this, it was curious to note the fact that if either agent was suspended, the pulse would rapidly increase in frequency, while under the combined influence of the two it was kept below 80 per minute."

PUERPERAL PNEUMONIA.

BY JAMES E. FREE, M. D.,
BILLINGS, MONTANA.

Mrs. S., primipara, was delivered of a female child weighing six pounds, May 23, 1890. She was a large, lank woman at the time of her lying-in, had been married about two years, and was thirty years old. Two months previous to this time she contracted the grippe, which did not develop any very serious symptoms, although it proved to be a tedious complaint. A slightly annoying cough was still present when labor set in. At 1 A. M., the sharp pains having lasted two hours, delivery was accomplished. It was an ordinary case, causing less suffering than is usual where the mother has reached such a mature age.

Some hemorrhage followed the shedding of the placenta, and ergot was administered to make the uterus behave physiologically. It is rarely necessary in a primipara, and in this case it might not have been so. However, it is a bold physician who will face a lot of old women and tell them to wait on Nature, when they know that a friend is bleeding. Two hours after delivery, the patient having brightened up considerably, a binder was applied, and the soiled clothing was removed. The woman's temperature at this time was 99°, her pulse 100. She expressed herself as comfortable while she remained perfectly still, and thought she could sleep. Between four and five o'clock in the morning I was summoned in great haste to her bedside. I found her suffering acutely with pain in the back. The pain was constant and located on both sides of the spinal column in the lumbar and dorsal regions, and it radiated downward to her feet. Not having had any similar experience, it was difficult for me to tell the origin of the trouble. Opium eaters are liable to have attacks of acute pains when they are in want of the drug, but here it did not seem as if the appetite was present. Ergot produces tonic spasm of uterine muscular tissue which is sometimes painful. Taking into consideration the amount of exercise the organ had undergone, it was not likely that fatigue would be the cause of the pain. When a set of muscles have been sharply used, or the use has been long continued, they show signs of exhaustion when moved. Perfect rest will generally partially relieve even

rheumatic pains. Here the uterus, after a normal labor, was contracted and at rest. The neuralgic symptoms were considered to be indicative of anemia of the cord. The woman's temperature was 98°, her pulse 96. A Dover's powder was ordered, which induced sleep and free diaphoresis. Several hours later she was put on Fowler's solution. The dull, colorless expression of countenance was similar to that of most victims of the morphine habit, and I thought more or less of the drug was necessary to a safe getting up.

Nothing of note occurred for several days. On the fourth day a decided rise of temperature was detected, morning 101°, evening 102°. The uterus was washed out three times in the next thirty-six hours, and antifebrin was prescribed. The patient was apparently comfortable until the physiological effect of the antifebrin became marked, when remarkable sweating, producing collapse, made it advisable to withdraw the remedy. Its anodyne effect was similar to that of the Dover's powder; but the latter seemed to fill the long-felt want for opium. Almost everything else nauseated the stomach when she had learned the effect of the ipecac and opium.

Two weeks after her confinement the patient was out of bed in a rocking-chair. She complained of so many troubles and seemed notwithstanding to be so strong, that she was allowed to get up. In the afternoon of this day she had an attack of acute pain in both legs. Her description of the pain, following the course of the large blood-vessels, made it probable that phlegmasic alba dolens was about to complicate matters. Fowler's solution and Dover's powder did not check the pain this time. Quinine could not be retained; neither could aconite. The temperature again went up to 102°. Lochial discharge was still present. The uterus was again washed out with warm water, but without any effect on the fever. Next morning a violent rigor, accompanied by intense internal congestion, came on, and lasted for two hours. Pain in the right side at the base of lung made breathing difficult and shallow. Auscultation and percussion revealed nothing abnormal. Blood-letting was indicated at this time as much as ever in my observation. However, as the lancet was wanting, also the cups, I concluded to fight it out with alcohol, mustard and hot water to the feet.

The next morning there were was almost complete percussion dulness on the right side, and an involvement of the lower border of the left lung. Pneumonia is said to be a treacherous disease, and if it was all this time manifesting itself in this case, it surely is entitled to that reputation.

The patient all along denied that she knew anything about morphia or opium, but the word of an habitué of these drugs is worthless. The temperature was 104½°, the pulse 150, the respirations 43. The aspect of affairs was very serious, and a consultant was asked for.

After an examination the consultant rejected the theory of opium eating, and suggested the administration of veratrum viride and a carbonate of ammonia mixture, with nothing hypnotic unless the cough was troublesome. The new treatment did not do well. Regular doses of brandy and cream and hypodermics of morphia at bedtime, to secure rest, was thought to be better, and consequently the consultant washed his hands of the case, and prophesied a speedy fatal issue.

It required eight weeks to establish convalescence. The temperature remained near 104° for seven weeks and then gradually subsided, and, as the fever left, a desire for food returned. Most troublesome of all the symptoms during the period was the dyspnœa, which showed itself every day, and threatened to terminate life, at first. Euphorbia pilulifera had recently come under my observation as a respiratory tonic, and its use in this case was beneficial. A half teaspoonful of the fluid extract given at the commencement of the dyspnœa, generally relieved it, but did not appear to have influence over its return. It was administered regularly latterly, and seemed to prevent the occurrence of the symptom. When expectoration commenced, the euphorbia was still a valuable remedy, seeming to promote resolution, and to act as a general tonic. While the difficulty of breathing lasted, its effect on the heart was analogous to that of digitalis, with more of a tendency to brighten the nervous force, and without any special action on the urinary function.

By October 1, the patient was in a lumber camp, away from drug stores, and with no opportunity to get opium. She had not yet entirely recovered health and strength; constipation was troublesome, headache was common and any kind of exertion was irksome and produced palpitation of the heart.

NEURALGIA FROM TOOTH-PRESSURE.

BY C. H. M. NEALL, M. D., D. D. S.,
PHILADELPHIA.

A gentleman called at my office on January 24, suffering with violent pain over the region of the left temple. The pain extended down to the angle of the inferior maxillary bone on the same side. I found, on examining the mouth, that he had erupted all of his teeth except the "wisdom tooth" on the right side, and upon making pressure over the gum in this region, that he experienced a great deal of pain. I found the gum and parts much inflamed. After satisfying myself that the tooth was the cause, I proceeded as follows. I made a free incision and found that the masticating surface of the tooth was deeply imbedded in the calcellated structure and pressing directly against the inferior maxillary division of the fifth pair of nerves. I extracted the tooth with some difficulty, and found that its root was exostosed. After removing the tooth, I syringed out the cavity with a 1-1000 solution of corrosive sublimate, and brought the parts together by means of a stitch. On January 27, the man returned to my office, informing me that the neuralgic pain he had suffered had entirely disappeared.

I have seen a number of cases like this in my own practice, and believe that we may many times trace neuralgic affections to cutting of the teeth.

PERISCOPE.

Dangers of Syringing the Ear.

In the *Atlanta Medical and Surgical Journal,* February, 1891, Dr. S. L. Philips, of Savannah, publishes an article in which he reports the case of a man, 54 years old, in fairly good health, save when suffering from bleeding piles, who for some weeks had experienced dulness of hearing on left side, and wished, if possible, to be relieved. On inspection, the canal of that side was found to be of average size, and containing a considerable amount of hardened wax. With a small rubber ball syringe, holding about an ounce and a half of water, filled with lukewarm water, Dr. Philips began to syringe the auditory canal. Several syringefuls forced gently into the ear not bringing away the wax, he used a little more pressure. Suddenly something seemed to give way. Water poured from the patient's left nostril, and he complained of a peculiar sensation in that ear, though he had no pain worth speaking of. The wax was loosened and easily removed from the canal. Dr. Philips thought, of course, he would find a perforation of considerable size in the membrane, the sequel of an old purulent inflammation of the tympanum, as sometimes wax forms over the opening, mixing with the secretions from the diseased mucous membrane, making quite a hard impervious wall to the secretions behind. When he looked at the drum-head he did not find what he expected, but one almost intact. It was congested in every part save the posterior superior quadrant. From the top of the malleus running down and back to the bony wall was a thin line of blood indicating the course of a recent rupture, and scattered here and there in its immediate region, a few drops of blood, which were easily wiped off with a piece of cotton wool. At this time there was no gaping. Under suitable treatment in two months the opening had closed, leaving only a thin line of scar, and hearing had become normal, he experiencing no inconvenience. Several months afterwards the membrane gave way at this point from too vigorous blowing of the nose, but the parts soon united without any treatment whatever than a piece of cotton wool worn in the canal for a while, since which time he has been all right.

In looking over the literature of the subject at his command, Dr. Philips finds but one case where rupture of the drum membrane took place from syringing the canal.

The above case teaches that one cannot be too careful in performing even this apparently trivial operation of syringing out the ear. Very great force is not necessary, and a powerful syringe is not needed. Some physicians have claimed that syringing could never do harm, provided only water was used, but Dr. Philips cannot agree with them. Only a short time ago Dr. Philips saw a little sufferer with chronic catarrh of middle ear and eczema of canal, the latter produced by an almost daily syringing for a year. The physician had diagnosticated wax accumulation, and given the mother directions to syringe out ear until she removed all wax. This treatment she kept up faithfully, but she never saw the wax in the returning water, and finally, when the ears

had become very painful the child was put under his care. After the usual treatment for aural catarrh, hearing was completely restored, but for a time the tendency to a recurrence of the eczema remained. While syringing is a good thing at times, its indiscriminate use is not good, and when it is necessary to use it, the greatest care and gentleness should be exercised. In purulent troubles of the ear, usually one syringeful of water will be sufficient to remove all *débris*, and when there is impacted wax a weak solution of bicarbonate of soda poured in the ear will, after several hours, so soften it that it can be removed without difficulty.

The Revival of Venesection.

The *British Medical Journal*, January 31, 1891, says editorially:

The discussion which took place at the last meeting of the Royal Medical and Chirurgical Society of London was in many respects interesting and noteworthy. Dr. Pye-Smith is to be congratulated on having so effectually succeeded in directing attention to a subject which must always have a real, if even only a historical, interest.

The reflections and conclusions contained in the paper were based upon the record of some fifty cases coming under the notice of the writer, in which venesection had been resorted to. The range of diseases in which it was employed included such acute affections as bronchitis, acute broncho-pneumonia, lobar pneumonia, miliary tuberculosis of the lungs, with others of more chronic nature, such as valvular disease of the heart with pericarditis, Bright's disease, aneurism and epilepsy; its value in other conditions, such as hemoptysis, apoplexy, uremic coma, was also considered.

The discussion which ensued was remarkable, on account of the almost complete unanimity which the speakers expressed in favor of the adoption of this method of treatment in suitable and urgent cases. All testified to the great and immediate relief which venesection gave under such circumstances—a relief unattended by any ill consequences on the subsequent progress of the disease.

Considerable differences of opinion, it is true, existed as to the cases most likely to be benefited by the treatment, or, rather, as to the cases which, in the experience of the various speakers, had most benefited by the treatment. For it was one of the noteworthy features of the discussion that there was a commendable absence of recourse to theoretical considerations as a basis for the practice.

In this respect the subject of venesection occupies a different position from that held by it in the former "bleeding era," to which reference was made in such humorous and instructive fashion by Sir George Humphry and Mr. George Pollock. The practice was then based on the humoral pathology which so long dominated the practice of medicine—that pathology which ascribes disease to the presence of deleterious agents in the blood, and which seemed, therefore, to justify the withdrawal of a certain quantity of the noxious blood as one of the best ways of curing it. As Dr. Broadbent pointed out, it was because the practice had been based so entirely on theory that it was carried to excess, and fell into such disrepute.

One of the chief merits of Dr. Pye-Smith's paper and of his subsequent remarks was to lay stress on the importance of resorting to venesection—not for the cure of pathological conditions as such, but for the relief of distressing symptoms depending on temporary alterations in the physiological balance of the circulation. As to the first indication laid down for the performance of the operation—cyanosis with distention of the right side of the heart depending on pulmonary or other obstruction to the circulation—there was a consensus of opinion favorable to the operation, but Dr. Broadbent did well to point out that before resorting to venesection under such circumstances, there should be evidence, as shown by the disparity between the strength of the heart's beat and the weakness of the pulse, that the right ventricle was still acting powerfully, and able to take advantage of the relief afforded it by the withdrawal of blood.

As to the second indication—the pain of aortic aneurism—the cases mentioned by Dr. Pye-Smith and Mr. Hulke, in which instantaneous relief was thus given, were very striking; and evidence of its curative effect on the aneurism was also incidentally adduced by Mr. Jonathan Hutchinson. Nevertheless, as Dr. Stephen Mackenzie pointed out, it may be doubted whether in iodide of potassium, nitrite of amyl and nitroglycerin, we do not possess remedial agents equally powerful and equally efficacious in relieving the high arterial tension on which such attacks of pain depend. The discussion, indeed, brought out the fact that it is

in relieving pain that venesection finds one of its best applications, and more especially in relieving the intense inflammatory pain of pleurisy, pleuro-pneumonia, or the severe pain with threatening onset of cerebral symptoms following injury to the skull.

To those accustomed, as most now are, to regard loss of blood, from whatever source, as an unmitigated evil, the suggestion to follow up an extensive bleeding from the lungs by a further bleeding from the arm, is startling. Nevertheless, something can be said, and was adduced by one of the speakers, in favor of its adoption in cases in which the patient is in urgent danger of suffocation from the reflux of blood into the bronchi. It is, however, peculiarly open to the objection brought against the operation of venesection generally—that in the present state of public opinion as to blood-letting, the discredit of a fatal result is too likely to be hastily assigned to the venesection. Apart from such considerations, however, the general result of an unusually animated discussion will be to direct attention once more to the possible advantages attending the judicious employment of a mode of treatment long condemned as not only useless but dangerous.

Beri-Beri.

A most interesting account of the nature and history of beri-beri is given by Dr. F. B. Sutcliffe in the *Occidental Medical Times*, February, 1891, after observations made in the Sandwich Islands.

Dr. Sutcliffe says: My first patients were Japanese. When I was asked to see them they were under arrest for having refused to work. They claimed to be ill, and the plantation doctor and the overseer claimed they were not. They were arrested, tried, found guilty and sent to the Wailuku jail. They had been driven about twelve miles through the dust and heat—not in a wagon, but a native policeman had ridden his mule, driving them ahead of him. They claimed that he had helped them along with the use of his whip, but I saw no evidence of such treatment, and did not think they were abused in that way. I was asked by the Sheriff to go and see them before they were locked up, as he thought they looked ill. When I saw them I did not know anything of their history. I was asked to examine them and say whether or not, in my judgment, they were ill. I found six of them sitting on a bench, looking worn out and very tired. They all had a temperature above the normal, and a rapid, full pulse. The heart was working hard, altogether out of keeping with the other symptoms. All were complaining of pain in the legs; one or two complained of pain in the chest, putting their fingers under the sternum, and pulling at it as if to lift it out. I, of course, pronounced them ill, but of what disease I only suspected, and refused to make any diagnosis until I had watched them for a day or two. I was then told their history, and I recommended that they be sent to the hospital instead of being put into a cell. I saw them again the same day, and all doubt as to the nature of the trouble was dispelled.

The further development of the disease was very interesting to watch. The legs of all began to swell, and later on this swelling became quite general, in one or two of the worst cases. The day after they were received, three of them were unable to walk without great effort, while the others were decidedly unsteady on their feet. The worst case amongst them assumed the gait and attitude of a child, who, in taking its first unsteady steps, fearing it may fall, puts out its hands as a safeguard, reels on one foot, bringing the lifted foot with undue force to the ground. The gait is peculiar; it seems to be an effort to balance and a false judgment as to distances, rather than a shrinking to ease soreness or pain in the legs or feet. I never saw a patient who seemed in danger of falling backwards; but this may be because, as I have said, they lean forward and put out their hands. The case that I have mentioned as being worse than the others did not improve. Effusion into the chest took place, the heart's action became worse, the kidneys did not perform more than half the work they should, breathing became more and more labored, and death took place in about one week from the time that he was forced to take his long walk to jail. The other patients gradually improved till they were able to leave for Honolulu, at which place I heard that one of them died and the others made a full recovery.

These cases were the most notable that came under my observation. They had been on the island but a short time, the vessel that they came in being still in port. The ship's surgeon visited them, and confirmed my diagnosis; indeed, they knew themselves what the trouble was, and spoke

of it as "kakae," the name they give to the disease.

For the next three years I saw a good many cases of all degrees of severity, though, as a rule, of a mild form, and yielding kindly to treatment. It was a common thing in visiting a plantation to find three or four cases of the disease. Usually the first symptoms of which they complained were swelling of the legs, pain along the tibia and shortness of breath. I would usually find upon examination, palpitation, a quick pulse and marked anemia. My method of treatment was as follows: I changed the patient's diet; where it could be had, milk was largely used, but it was scarce, and the Japanese do not like it. Fresh vegetables were given, and the best of all that we could get was tomatoes. The people most affected were in the habit of eating a deal of rice, salt fish and such oily preparations as the Chinese delight in. Where they could be persuaded to follow out the directions, improvement was the rule from the first, if the disease was not too far advanced when first seen. Occasionally a case would grow worse and have to go the hospital; some would fail to report for treatment after a slight degree of improvement, and, getting worse, come again and again, with the disease in a chronic form.

The drug that I gave oftener than any other was digitalis. I often combined with it the citrate of potash, and when the tongue had cleaned iron was given, and sometimes nux vomica. I was much impressed with the good effect of changing the patient's place of residence, when they were living in a low, wet locality, to a high and drier location. Where this could be done, and when they were well cared for in the matter of diet, the disease was often checked without other treatment. I can recall one case in a woman, a Japanese. She was ill for some time, but finally recovered. She had worked in the field with the men, and was exposed in the same way to like influences. I do not see why the disease should not attack the female, but this is the only case in a woman that I can remember. I never saw a child affected, or a white man, or a native Hawaiian. All my cases were Japanese or Chinese. If Kynsey is correct in his observations of the disease in Ceylon, we must conclude that it differs from that at Hawaii; for the women and children drink of the same water that is supplied to the field hands, and would be just as apt to receive any parasite that it might contain, and as likely to suffer from any disease caused thereby, and this is equally true of the foreigner and of the native.

We have seen that research by those who have had the opportunity of making *post-mortem* examinations has not yielded the results that one might hope to find in a disease in which so many symptoms point to grave changes in the great nerve centres. I think that the paralysis is due to a starved condition of the cord rather than a changed one, and that this condition is due, in part at least to the anemia. The gait, in many cases, is very much like that of ataxia, and I cannot believe with Kynsey, that the embarrassment in this respect is due to the edema of the lower extremities, as I have seen it come on before this was at all marked.

My observation would lead me to conclude that the disease is not as severe in Hawaii as in other countries, and that the worst cases seen there are brought into the country in a more or less advanced stage. While beri-beri is a disease of other lands, we have three cases reported by Dr. Seguin, of New York, in 1888, and I do not see why cases might not be found on this coast almost any time. I have inquired of an intelligent Japanese, of this city, if he had ever seen a case of beri-beri in this country, and he stated he had seen two in San Francisco. This may or may not be so, but to me it seems very probable, for the Japanese understand the disease, its symptoms and its gravity very well.

Chloroform in Tracheotomy.

The *Medical Press*, January 28, 1891, says: A curious fatality attaches to the administration of chloroform in operations on the throat, and this has been noticed more particularly in connection with tracheotomy. So tangible is the risk to which the patient is exposed that it really becomes a question to be seriously discussed, whether the use of chloroform is justifiable under these circumstances. The operation of tracheotomy, when skilfully performed, is short and not very painful, and is most frequently necessary in young subjects, the victims of some laryngeal affection, hence in patients physically well under control. It is, moreover, most commonly performed in order to avert impending asphyxia, and the patient is usu-

ally already suffering from partial deprivation of oxygen, the effects of which are undoubtedly to dull the perception in respect of pain.

On the same subject the *British Medical Journal* (Supplement), January 31, says: M. Geffrier, of Orleans, has recently published (*Revue de Chirurgie*, December, 1890) a paper on chloroform in tracheotomy. The views of this author, which are based on a study of eighty-seven cases, are summed up in the following conclusions: (1) Chloroform is of unquestionable service in tracheotomy on children; (2) its use is not attended with any special danger in this operation, provided that attention be paid to certain contra-indications; (3) the following precautions ought to be taken: (*a*) everything that might be required in the course of the operation should be placed close at hand; (*b*) the administrator, who ought to be experienced in the use of chloroform, should carefully watch the respiration, and, if it be required, excite the respiration by speaking to the patient or by irritating the skin; (*c*) if the state of the respiration become alarming, the inhalation of chloroform should be discontinued at once, and the operation be performed without delay. Extreme asphyxia and prostration from diphtheritic poison are regarded as absolute contra-indications. Marked cyanosis without, and slight cyanosis with impeded expiration are both regarded as contra-indications, though not so stringent as the conditions previously mentioned. Slight cyanosis without obstructed expiration and a very early age are not regarded as contra-indications. In the author's opinion, if the operation be not contra-indicated by the age of the infant, neither will the inhalation of chloroform be contra-indicated.

Hyperemesis and its Treatment with Creasote.

In the *Berliner Klin. Wochenschrift*, December 29, 1890, Dr. Peter Kaatzer has a short communication on the rationale of the treatment of hyperemesis with creasote. He remarks that the therapeutics of this affection have not so far reached definite results. Starting from the supposition that the disease is a reflex neurosis, the narcotics were brought into employment and their achievements praised. According to Eulenburg and Lemaistre, iodide of potash does excellent service. If one holds Kehrer's view, that the obstinate vomiting of pregnancy is occasioned by severe diseases of the stomach, then therapeutic measures must be adopted accordingly.

Kaatzer gives a report of a case in which a woman was thought to be wasting from phthisis. Her sputum contained only a few bacilli, and it came out by and by that the woman was pregnant, and was vomiting after every meal. Kaatzer prescribed creasote, both for the stomach trouble and the phthisis. After taking two doses, the patient ceased to vomit and rapidly recovered. Kaatzer does not know why the remedy did good. The formula used was the following:

℞ Creasoti puriss. . . . . ♏xxx
Alcoholis . . . . . f℥i
Tinct. gentianæ . . . . . f℥iiss
Ext. caffeæ . . . . . ℥iiss
Aq. destill. . . . . f℥iii
M. Sig. Shake well. Tablespoonful in milk.

Chromic Acid in Habitual Epistaxis.

In the St. Petersburg semi-weekly *Meditzina*, No. 51, 1890, p. 413, Dr. Metchislav V. Pogorelsky, of Elisavetgrad, relates three cases of obstinate habitual epistaxis in school boys, in which, following, Dr. Heryng's recommendation, he successfully resorted to cauterizing with crystalline chromic acid, after all ordinary means had failed. In all the three patients, a rhinoscopic examination revealed the presence of a small-sized, sharply circumscribed highly-vascularized area situated on the nasal septum. Only this congested spot was treated with the acid, the application being repeated once or twice a week and always followed by washing out the nasal cavity with a weak solution of chloride of sodium, or bicarbonate of soda, or borax. In two of the cases 4 or 5 *séances* proved sufficient to effect a complete and permanent cure; in the third a few more applications become necessary to obtain the result.

Fissured Nipples.

Scarff recommends for fissured nipples the following application.

℞ Balsami Peruviani . . . . . f℥ss
Tincturæ arnicæ . . . . . āā f℥ss
Olei amygdalæ dulcis . . . . . f℥j
Aquæ calcis . . . . . f℥ss
M. Ft. Linimentum. S. Apply locally.

—*Journal de Médicine*, January 25, 1891.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,

EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

CONCEALED ADVERTISEMENTS IN MEDICAL JOURNALS.

For nearly four years the MEDICAL AND SURGICAL REPORTER has steadfastly endeavored to do its share towards elevating the tone of medical journalism in the United States, by rigidly excluding from its pages what are called "reading notices" and every other form of more or less concealed advertisements. It has also made appeals to other medical journals that they would assist in maintaining this standard. It is with great regret that we have observed from time to time that journals issued by wealthy publishing houses have not been willing to adhere to the same principles, and that they have published matter which had been sent by advertisers presumably to many of the medical journals in the United States, and which was certainly sent to the MEDICAL AND SURGICAL REPORTER, and refused admittance to our columns. A recent illustration of this kind was furnished by one of our contemporaries in November, 1890, which contained in its editorial columns an article that the REPORTER had refused to publish, for reasons which we think ought to have kept it out of the columns of a journal which is, on most points, of such high standing. When the Editor of the journal referred to had his attention called to this occurrence, he made a courteously worded reply that the editorial pages of his journal "are not purchasable," and that it never publishes anything referring to a special remedy "unless the article possesses something of scientific interest."

"With this," his letter concluded, "we will drop the subject." Now this the REPORTER regretted, and it also regrets to see in a recent issue of the same journal, a long article, which we presume was sent to the Editor—as it was to the Editor of the REPORTER—by one of our most valuable advertisers. Exactly five hundred powerful advocates pleaded with us that this article was "of scientific interest," but we wrote to the advertiser stating our rule and declining to relax it.

As the REPORTER remarked long ago, in speaking of this subject, we can understand how medical journals which have a hard struggle to maintain their existence may yield to the pressure of advertisers; but we cannot understand how journals which are supposed to be prosperous and strong, can publish, in columns supposed to be devoted exclusively to scientific matter, articles which are prepared for them by advertisers, and which are themselves most palpable advertisements. The rule of the REPORTER in this has been invariably to refuse this sort of matter, taking the ground that its Editor is unwilling to assume so much for his intelligence and his conscientiousness as that he could enter upon so dangerous a course without risk of error on his part or deception on the part of his readers.

We wish that all the medical journals in

the country would adopt this principle—if it be admitted to be a correct one—or, at least, that the strong journals should not do what makes it harder for weaker ones, which would like to do right, to resist a very urgent form of temptation.

FILARIA SANGUINIS HOMINIS.

The occurrence of the conditions known as chyluria, as elephantiasis, and as lymph-scrotum has long been recognized. It is, however, only within comparatively recent years that their common etiological relation has been established. Wucherer, in 1866, found microscopically in the urine of a patient with chyluria a number of minute worms. In 1872, Lewis discovered the same parasites in the blood of man, and gave to them the name *filarila sanguinis hominis.* These were taken to be the embryos of a nematode or round worm, the parent being first detected by Bancroft, in 1876. The literature on the subject has grown to considerable proportions, other contributors having been Manson, Cobbold, MacKenzie, Leuckart and recently, Guitéras, Mastin and De Saussure.

In the *New Orleans Medical and Surgical Journal,* for January, 1891, Dr. Rudolph Matas reports a case of chylocele into the vaginal tunic of the testicle, due to the presence of *filaria sanguinis hominis,* and reviews at length the whole subject.

The parasite is found principally in the tropics, in Brazil, in Egypt, in the Indies, in China, in Australia. It has been found in isolated cases in the Southern United States. The fully developed worm is from three and a half to four inches long, and about a hundreth in diameter, while the embryo is about one hundredth in length and one thirty-two-hundredth in diameter.

The mature worm gains entrance into the human organism with the drinking water. It bores its way through the wall of the stomach or bowels into the lymphatic system, at some point of which it becomes intercepted and here propagates its offspring. These are carried by way of the thoracic duct into the general circulation, in which they can be detected during the periods of rest ordinarily at night, but by day if the patient is active by night and rests during the day. The embryos may circulate in the blood still enveloped in their capsules or they may be set free. In the former condition the ova are too large to pass through the lymphatic system, and are somewhere detained, giving rise to lymph stasis in the circulation behind them.

In this way, depending upon the location of the obstruction, the various conditions of chyluria or hemato-chyluria, chylous hydrocele, lymph-leg or lymph-scrotum may arise. It seems not impossible that effusions into the serous cavities may take place, occasioning chylothorax or chylous ascites. The embryos do not attain mature development in man, but for this require the intermediation of another host. This office is performed by the mosquito. In its depredations, with the blood it removes, it also carries away some embryo filariæ. The mosquito having hatched its own ova, dies and deposits both these and the now maturely developed filariæ upon the water.

Individuals harboring the filaria may enjoy a fair degree of health, notwithstanding the local manifestations. The condition may exist for many years, even beyond fifty. It is not itself directly fatal, except by its complications. Recovery is the rule and may be spontaneous. As the disease has its home in warm climates, removal to colder regions may suffice to effect a cure. The prophylaxis thus becomes a most important matter.

The danger is less from running water, from that obtained from springs and artesian wells, and greater from still water, in reservoirs, cisterns or tanks. In places in which filariæ are known to abound, the water should always be boiled. Filtering or straining alone ought not to be relied upon.

DIGESTION FOR ABSCESS CAVITIES.

At the last meeting of the Medical Society of the State of New York, Dr. Robert T. Morris, of New York, in a paper on the action of trypsin, pancreatic extract and pepsin upon sloughs, coagula and muco-pus, stated that the surgeon's resources were materially enlarged by adding the digestive ferments to his armamentarium, and with them liquefying putrescible material, like the lining membrane and lymph coagula and necrotic tissues of tuberculous abscesses.

He stated that, contrary to the presupposed ideas, pepsin is the best liquefier. This material, which is perfectly harmless in any proportions, can be best used in a ten per cent. solution in water, acidulated with one per cent. of hydrochloric acid. The patient should assume a position favorable for the retention of the solution, and at the end of an hour the liquefied dead tissues may be washed out, and the cleaned abscess may be then easily sterilized with peroxide of hydrogen.

Pepsin, Dr. Morris said, will liquefy dead tissues in the deepest recesses of tuberculous abscesses, and its action is ended abruptly as soon as it reaches tissues through which blood is circulating. Various conditions of disease tissue suitable for pepsin treatment were referred to in Dr. Morris's paper, and he was inclined to expect some advantage from association of the method he advocated with the use of Koch's "lymph;" for he took it as demonstrated that Koch's lymph would loosen and throw out masses of necrotic tissue, and that these could then be reached with pepsin and peroxide of hydrogen—giving the surgeon an ideal group of materials represented by three P's—paratoloid, pepsin and peroxide of hydrogen.

The first part of Dr. Morris's suggestion we think deserves careful consideration. That is, that the solvent power of pepsin upon dead albuminoid matter may be utilized with advantage in the treatment of tuberculous abscess cavities and sinuses. The idea is not a new one but it has never been carried very far as yet; and we commend it to the notice of the readers of the REPORTER, for its simplicity and ease of execution.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

LEHRBUCH DER KLINISCHEN ARZNEIBEHANDLUNG. Für Studirende und Arzte. VON DR. FRANZ PENZOLDT, Ordentlichem Professor und Oberarzt der Medicinischen Poliklinik zu Erlangen. Zweite veränderte Auflage. Jena: Verlag von Gustav Fischer, 1890. Royal 8vo, pp. xxii, 268.

TEXT-BOOK OF CLINICAL THERAPEUTICS. For Students and Practitioners. BY DR. FRANZ PENZOLDT, Professor Extraordinary and Physician in Chief at the Medical Polyclinic at Erlangen. Second revised edition.

The first edition of this work is dated June, 1889, the present, the second, April, 1890. The book seems to have supplied a want in the German medical profession. A good deal of consideration has been given to the most recent drugs, some of which, it is true, have already proved themselves valuable medicinal agents, while, of others, the utility is, as yet, at least doubtful. The arrangement of subjects is somewhat different from that to which English readers have become accustomed since the advent of the physiological method in the study and administration of remedies. Two great divisions are made: inorganic medicaments and carbon compounds. Under the former are presented metals and non-metals; under the latter, in many subdivisions, the remainder of the subject. The topics are discussed with regard to the characters and properties of the drugs, as to their physiological actions, their toxicology, their therapeutical applications and their diagnostic value. Many of the opinions expressed are at least not generally accepted among us, if not at variance with our views, while some therapeutical applications of considerable importance are quite ignored.

Of bismuth it is said: "Despite its ancient reputation, its therapeutical utility in various directions is not above doubt." It is not thought to be efficacious in gastric ulcer. "Only in certain cases of chronic diarrhœa, given in large doses, have certain otherwise skeptical observers reported good results." It may be easier to treat acute and subacute attacks of gastro-intestinal catarrh, with nausea, vomiting and diarrhœa, by means of opium, but bismuth is certainly the safer remedy. Chloroform is said to be less dangerous as a general anæsthetic than ether. Antipyrin is described as having almost a specific action in acute articular rheumatism.

The general indication for the administration of digitalis is persistent cardiac weakness and its consequences. The most important question is: Is the arterial tension subnormal? Such a condition is usually associated with a small, irregular or frequent pulse, but not necessarily. The pulse may be regular and infrequent, yet digitalis may be indicated. The utility of digitalis consists in the restoration of the ruptured compensation, the removal of the œdema, of the cyanosis and of the dyspnœa.

Strychnine, it is said, may do good in certain am-

blyopias and amauroses, but it has no other significant therapeutic value. Strychnine is one of our most reliable and active cardiac stimulants, and is useful as a tonic in asthenic conditions. Nor is atropine given a therapeutical place as a prompt and efficient cardiac stimulant.

The claims of gelsemium as a remedy for neuralgia, especially of the inferior maxillary type, are rejected. The only indication given for the use of pepsin is total absence of the gastric ferment, such as occurs in atrophy of the mucous membrane of the stomach. Even in these cases, its utility would be doubtful because of the lessened absorptive activity of the mucous membrane. The good results obtained in erysipelas by the use of pilocarpus and pilocarpine are not alluded to. The preparations of aconite are said to be not useful. The administration of aconitine in neuralgia cannot be recommended.

The work may be a true reflex of German therapeutics, but it presents many variations from our own. We have only noted some of the most striking differences.

ŒUVRES COMPLÈTES DE J. M. CHARCOT. Hémorragie et Ramollissement du Cerveau; Metallothérapie et Hypnotisme; Électrothérapie.

COMPLETE WORKS OF J. M. CHARCOT. Hemorrhage and Softening of the Brain; Metalotherapy, Hypnotism and Electrotherapy. Volume IX. Thirty-four illustrations and thirteen plates. 8vo, pp. viii, 571. Paris: Office of the *Progrès Médical*, 1890. Price, 15 francs.

This volume contains Prof. Charcot's writings upon cerebral hemorrhage, which he believes to be due, in the majority of cases, to miliary aneurisms of the small arteries of the brain. Abstracts of eighty-seven cases are given in support of his opinion. As regards softening of the brain, he accepts the view which attributes the softening to an alteration of nutrition following upon embolism, atheroma or thrombosis. There are also important papers on joint-diseases apparently due to diseases of the brain and cord. The second part of the book is devoted to metaloscopy, metalotherapy and hypnotism. In the third and concluding part, Prof. Charcot speaks of electrotherapy, and especially of the use of static electricity in medicine.

The whole book is a mine of information, and will prove invaluable to students of nervous diseases.

Notes and Comments.

Congenital Occlusion of the Urethra.

An interesting example of congenital obstruction to urination is given by Dr. James Adams, of Eastbourne, in the *British Medical Journal*, January 31, 1891. Dr. Adams says: My attention has been directed to this rare condition by a case which occurred in my practice in October, 1889. I attended a confinement, and after a natural labor a male child was born at full term, who was well formed, and in every respect apparently normal, except he was the subject of hypospadias. Two hours afterwards I was sent for to see the child, because the nurse, who was a trained and intelligent woman, thought something was wrong, as the infant, although he had been bathed and dressed, and had passed a motion, had not micturated. The meatus was patent, so I tried to pass a small blunt silver probe down the urethra, but it would go only a very short distance. I directed the nurse to give the child a warm bath and keep him in the water for fifteen minutes, and to repeat the bath two or three times during the next twelve hours if no urine passed.

The next morning, fifteen hours after birth, I found that no urine had been passed and the child was beginning to be restless and uneasy, but without symptoms of distress. I again tried to pass, with all gentleness, the silver probe, and failed to get it further than the previous attempt. I now took a small French catheter, and that seemed to be brought up at the same distance from the meatus. Being a non-metallic instrument, I used as much force as it would bear, but did not succeed in getting beyond the obstruction. I withdrew the catheter and tried again, and this time succeeded in penetrating what I believe to have been a thin membranous structure which was occluding the urethra. The urine came freely through the catheter, and I had no further trouble with the case.

It is open to remark that the urethra might not have been occluded, being merely narrowed by a congenital stricture, or that the urethra was of normal caliber, and that its sides were agglutinated by inspissated secretion. While I am unable to disprove either of these opinions, I may say that had it been a stricture I should have expected subsequent trouble, and had it been the other condition I should have expected the hot baths externally, and the effect of the warm urine internally on the vesical side of the obstruction to have caused its disappearance. Another point tending to support my view that it was an organic occlusion of the urethra is the fact of the infant being a hypospadian, showing some developmental abnormality of the mesoblast in this region. And in a case of congenital occlusion reported by Mr. Forster, of Darlington, in the *British Medical Journal* of January 3, 1885, the infant was also the subject of hypospadias.

The only other instance I have met with of this condition was in 1878. This was a

premature child, born at seven mouths, and a weakly specimen for that age. I was unable to pass a probe or catheter, and the child died forty-eight hours after birth, never having passed any urine. The child was too feeble to bear any further surgical proceedings, even if the parents would have consented.

The literature of this subject is very scanty, and in several of our English text-books no reference is made to it. American works contain the fullest account of it, and I quote the following by Professor Duplay from *The International Encyclopædia of Surgery*, edited by John Ashhurst, M. D. :

"These occlusions, which result from gluing together of the two corresponding halves of the penis, may occupy any point in the canal, but the meatus urinarius is the seat of election. Sometimes the mucous membrane of the glans is seen to pass in front of the meatus without anything being seen at this point which could indicate the existence of an orifice. . . . Most frequently the meatus is well formed, and ends in a *cul de sac* at a distance of a few millimeters. We have only a very small number of examples of occlusions situated at other points of the canal. The diagnosis is especially easy when the occlusion is in the meatus or in the fossa navicularis. Deeper occlusions may escape the first examination, but the effectual effort of the infant to urinate, and sounding with a curved stylet or very small catheter will usually render error impossible."

I will also give the short description found in Gross's *Surgery :*

"The most common of these congenital vices are first closure or contraction of the meatus ; and, secondly, absence, contraction and change of form of the urethra. Occlusion of the external meatus always demands prompt interference. When it is caused simply by a duplicature of the lining membrane forming a sort of hymen, a vertical incision in the direction of the natural outlet is generally all that is required, the edges of the wound being kept asunder by means of a bougie. When the imperforation depends upon the presence of fibrous tissue and reaches a considerable distance back, the operation will be more serious, and will require to be performed with a trocar."

The diagnosis in these cases is easily made, for the subjects are newly-born infants who are unable to pass water, and if the obstruction is at the meatus the condition is at once recognized, and if the obstruction is further down the urethra, the use of the catheter makes it evident. If the surgeon is unable to penetrate the obstruction by means of a soft catheter, he cannot judge how far the occlusion extends between the point where the catheter is brought up and the bladder, as it may involve the whole of that portion of the urethra, or only a small part of it.

On the question of treatment the proper course to adopt is clear where the occlusion consists of a membranous veil covering the meatus. This veil must be incised, and the orifice kept patent by passing a bougie daily for a week or ten days. Also in cases similar to mine, where a non-metallic catheter can be with moderate force thrust through the soft and easily lacerable membrane occluding the urethra, this treatment is clearly the one to follow ; but in those still rarer cases where the urethra is obliterated for some distance, it appears to me there presents itself to the surgeon a most unfavorable condition to deal with satisfactorily.

Three courses are open, namely (1) forcing a passage by means of a curved stylet, or small curved trocar and canula; (2) perineal cystotomy; (3) suprapubic puncture. The objection to forcing a passage is that it is an unsurgical and hazardous proceeding, and that you are working in the dark and have no guide to rely on. If you reach the bladder so much the better for your patient, for your treatment saves his life and leaves him with a urethra in its normal position.

Another agument in favor of this course is that it has been adopted with success, notably in the case mentioned above, where the urethra was said to be wholly obliterated. With regard to perineal cystotomy by the median method with the finger in the rectum, the distance to reach the bladder is short, and as it would be distended, one would feel more certainty of finding it than by the first plan. But I should give the preference to suprapubic puncture by small trocar as being simplest and safest, and I should fix in a rubber catheter and wait upon events. Afterwards, when the child was old enough, the suprapubic opening might be enlarged, the bladder explored, and a passage made from its interior by means of a curved trocar and canula as near along the normal position of the urethra as could be ascertained.

Medical and Social Aspects of Abortion.

At the Third General Meeting of Russian Medical Men at St. Petersburg, Dr. Natalïa V. Thalberg, a woman doctor of Kïev, read a communication (*Proceedings*, No. 8, 1889, p. 256) on criminal abortion, and a rational struggle against that steadily progressing social evil. She says that a considerable number of cases of artificial abortion give rise to grave and permanent disturbances in the woman's health, not unfrequently ending in death. Both in Western Europe and also in Russia, criminal abortion has at present attained great dimensions and manifests unmistakably a harmful influence on the health of the population. A truly regretful circumstance is the increasing assistance in the matter rendered to women by the members of the medical profession; and its ill-effect is enhanced by the fact that often medical art proves powerless to obviate the injurious effects of the abortion it produces, due especially to a hasty and clumsy performance of the operation, and also to the violation of elementary rules of precaution during the after-period. Apart from austere views entertained by modern society in regard to an extra-matrimonial pregnancy, and from increasing poverty, the main causes of a progressive increase of abortion are: defective moral and mental education of women, and woman's ignorance of the criminality of abortion, and especially of its harmful effects on her own health. An indirect but still powerful cause of the spread of abortion is found in the defective sense and principles of those members of the medical profession who render their assistance in the matter.

In view of these facts, a rational struggle against the evil demands joint action by the authorities and by the medical profession. The initiative in the matter belongs undoubtedly to the profession, since the medical man, whom both married and single women solicit to procure abortion, knows best the consequences of its performance. Hence, an imperative duty arises for the profession to draw the attention of the community to the evil, to elucidate its causation, and to find out effective means for its prevention.

Dr. Thalberg suggests the following measures to restrict criminal abortion: 1. To reduce to the lowest point possible the legal punishment of women who have abortions performed, since severe laws have not served to prevent them from undergoing the operation, while they act powerfully in restraining them from denouncing the abortionist. 2. To disseminate knowledge of the injurious effects and dangers of abortion, by means of pamphlets, public lectures, etc. 3. To establish numerous lying-in hospitals and homes for foundlings all over the country. 4. To promote the education of women tending to elevate their mental and moral level.

[Our Russian translator suggests that we may take the liberty to express doubt in regard to the actual degree of effectiveness of measures proposed by Dr. Thalberg. Obviously, her measures are nothing else than mere palliatives. However humane, they do not touch in the least the cardinal etiological factors of the social evil. Those factors are (1), in Russia, an appallingly progressing wholesale pauperism which, on one hand, makes the establishment of a "legal" family less and less accessible, because of its expensiveness; and, on the other hand, converts the appearance of every child into a true disaster, and (2), the ethically immoral moral codex of the modern "civilized" community, which sentences to social death every unhappy woman who, having no possibility or opportunity for establishing a "legal" home, gives way to temptation to the performance of her sexual functions. He says that only those measures can prove effective against the slaughter of intra-uterine children, which honestly and courageously strive to improve the economical conditions of the community and to humanize the moral codex of the latter. None of the great social evils undermining the modern community can possibly be remedied by moralizing or by legal and hygienic trifles which leave intact the essence of the matter.]

Country Practice.

In the *Medical World*, March, 1891, there is a letter from Dr. George R. Robbins, of Hamilton Square, N. J., which gives a description of some of the experiences of a country practice, which we are sure will be read with interest and sympathy by many of the subscribers to the REPORTER.

Of obstetrical work Dr. Robbins, who has been in practice twenty-one years, says: "You will be taught not to approach an obsteteric case without fortifying yourself with

an armful of instruments, carbolized silk to tie the cord, bichloride for washing hands, iron, ergot, chloroform, morphine, turpentine, quinine, etc.—a whole bagful of bottles —all good. They will serve you if you have the money to buy them. I have attended cases of confinement after waiting for hours asleep in a wood-box behind the stove; not a rag to dress the child; tied the cord with a piece of my shoe-string, cutting the cord with an old rusty butcher knife, all with good results.

"Imagine yourself summoned to attend a case of labor. You approach the house with your grained leather obstetrical bag, containing forceps, craniotomy instruments, blunt-pointed scissors, spring lancet, carbolized silk, absorbent cotton, drugs as enumerated above, etc. You enter the waiting room, carpeted with brussels, with velvet plush reclining chair, with foot-rest before the grate. You are informed that you are the sole possessor of that room when not required in the adjoining one. At the proper time you approach your patient, notice all silk-lined paraphernalia for little 'teetsy-weetsy,' with all kinds of powders, puffs, pastes, etc. When your blessed one is comfortable you are furnished with warm diluted Florida water and bouquet soap to wash with, and May-bloom to complete your toilet. Splendid. But you may thank your stars if you do not get your sleep in a wood-box, and after the earth has been gladdened with that familiar 'squall,' go down to the ditch and wash your hands the same as I have done. I have made my splints for fractures from barrel staves, shingles, cigar boxes, leather, pasteboard, anything. I performed my first craniotomy alone, delivering the child, weighing sixteen pounds, saved the mother, all with a jack-knife, which I borrowed from the woman's husband, and my tooth forceps. Why did I do it with these tools? Because I had no proper instruments and was too poor to buy them at that time."

New Method of Detecting Tubercle Bacilli.

The *Lancet*, February 7, says: Dr. Biedert, of Hagenau, in Alsace, has devised a new and considerably surer method for the discovery of tubercle bacilli in sputum. He collects a tablespoonful or more of the sputum, mixes it well with a glass rod, takes some of it and stirs it together with two tablespoonfuls of water and four to eight drops of solution of caustic soda according to the density of the sputum, and then boils it, stirring it the while in a shallow cup, gradually adding four to six tablespoonfuls of water till he gets a pretty thin fluid mass. This he allows to stand for two hours in a high glass tapering as finely as possible downwards, and all the formed particles sink with the tubercle bacilli to the bottom. Then he pours off the fluid, retaining the sediment, parts of which he takes out with a platinum needle and rubs them fine on a cover-glass. When the preparation is dry he passes it through a flame, stains it with a carbolized solution of fuchsine, and then bleaches it with 25 per cent. sulphuric acid. If there are any tubercle bacilli they remain red, and are thus distinguishable under the microscope. Even a single bacillus is discoverable in this way, whereas the older methods yielded a positive result only if there were many.

Trained Nurses.

In an address delivered before the Boston City School, an abstract of which appears in *The Nightingale*, January 31, 1891, Dr. Chas. M. Green makes some timely remarks upon the duties and conduct of the trained nurse. He says:

The nurse's duty to the patient consists chiefly in faithfully carrying out the physician's directions, in accordance with her previous training, unless the doctor specifies other methods.

The nurse's manner in the sick-room should always be cheerful and hopeful. No matter how grave the case, she should never betray in her face or manner the anxiety she may feel. She should hold no long or whispered interviews with the physician, or members of the family, within sight or hearing of the patient: such conduct always excites suspicion in the patient's mind that his case is not progressing favorably, and deepens the forebodings which patients are prone to cherish. She should never announce in the sick-room the patient's temperature, or give other information about the case than that which is favorable and encouraging. Her report to the physician should be made in an adjoining room. Startling news or private grievances should never be made known in the sick-room. All medicines and other appliances of the sick-room should be kept in an adjoining chamber; but if this is impossible, they should be neatly ar-

ranged upon a table, and perhaps hidden with a screen; some patients have a horror of gazing upon the cups, bottles and spoons, which remind them of their condition.

Unless the continued presence of the nurse is necessary in the sick-room, she should leave the physician alone with the patient during a part of his visit. There may be some confidences between patient and doctor which it is desired she should not share. When members of the family visit the patient, if that is allowed, the nurse should withdraw for a time, for obvious reasons; this will give her time for rest and relaxation, and the patient an opportunity for a few minutes' privacy with his family.

As the patient enters upon his convalescence, he usually begins to take a lively interest in what he can eat, or he may be led to do so. Then the nurse has an opportunity to use her taste in the serving of his food; for we all know how much better everything tastes when it is daintily served.

Above all things, the nurse should not gossip. Patients will often listen with the greatest interest to what she may say of other cases and people, and then wonder afterwards whether she will not, at her next case, portray the scenes of their sick-room. A high-minded nurse should remember that she has no right to trifle with the sacred confidence of the sick-room, or carry beyond its walls the private affairs which have necessarily come to her knowledge. The nurse should not at first seek to displace from the sick-room members of the family who are in attendance upon the patient; they are often loath to give up one dear to them to the care of a stranger, and unwilling to be directed by the nurse. She should, therefore, manifest her willingness to assist them, and gradually they will perceive that she is far better fitted than they for the duties of the sick-room, and will gracefully yield to her the position which it is her province to occupy. A nurse should be willing to go beyond the limits of her legitimate work, if she can do so without neglecting her proper duties. It always pays to be obliging in every walk of life; and the nurse who is willing to wash some needed article of dress, to bind up a sore finger, mend a broken shoe string, or sew on a button, will be popular in any household. All that has been said about gossiping in the sick-room applies with equal force in the household. Family secrets will necessarily come to the knowledge of the nurse, and she should guard them as religiously as those of the patient; her duty in this respect is the same with that of the doctor.

The nurse will generally be asked where she wishes to take her meals; the reply should be: "Wherever it is most convenient to the family," adding, "in the dining-room, after the family is served, if it is agreeable." If the family breakfasts late, however, she may ask to have her breakfast earlier. It is probably not agreeable to the nurse to eat with the family, even if she is asked to do so; and if so asked, it would be right for her in a quiet way to mention one of the many reasons why she had best not do so. When the patient is very sick, it may be necessary that the nurse should be served on a tray in an adjoining chamber. Sometimes the nurse is expected to eat in the kitchen. It is well to advise the family that it is best that the nurse should be in the kitchen as little as possible; and that if she has to eat with the servants, it will be hard for her, without giving offense to them, to remain loyal to her duty in respect to the secrets of the sick-room. When, however, the nurse's duty takes her to the kitchen, perhaps to prepare some article of food for the patient, she should always greet the servants kindly, and assume no superiority. A nurse can, by her gentleness and tact, so win the regard of a large corps of servants that they will almost bow down and worship her. Such a nurse is never without engagements, and does much to increase the demand for trained nurses in the community.

Control of Sources of Water Supply.

The *Engineering Record*, February 14, 1891, says:

The question of the control of sources of water supply is one of great and increasing importance, and the necessity of obtaining an abundant supply of pure and wholesome water for household use is a universal one. In sparsely settled districts of this country, or in small communities, it is usually an easy matter to obtain it from local springs or properly located wells. But when small communities have grown into towns, and towns into cities, many difficulties are encountered. Local sources of supply become contaminated, and the demand being a large and concentrated one, the supply frequently has to be sought at considerable distances. Even then, especially in the more thickly

settled portions of the country, it requires constant care to keep the sources of supply free from defilement.

The right to the use of water for the supply of cities and towns must necessarily take precedence over all individual or corporate claims to ownership for manufacturing or other purposes, and it is generally the case that communities, seeking a public supply, are authorized by State legislation to acquire, by the right of eminent domain, any water that may be needed for this purpose, paying, of course, for all damages sustained by mill owners or riparian proprietors from its appropriation or diversion.

With the danger of this constantly increasing demand producing a scarcity of wholesome water available for city uses, it seems important that some steps should be taken to guard against undue appropriation of sources of supply by one city, far beyond its present needs, and at the expense of other cities in the same State; and still more against the monopoly by syndicates of all desirable sources of supply in a State or district, for the purpose of "making a corner" in water and compelling the cities to buy of them, in one form or another, at a greatly enhanced cost. We have constantly advocated the desirability of cities owning their own systems of water supply when practicable; still we have been willing to acknowledge that there are cases in which private ownership is admissible, since otherwise, for various reasons, the construction of the works would be indefinitely postponed—and a private supply is certainly better than no supply at all. The legal incorporation, therefore, of a private company for supplying water to a given place, endowing it with the necessary powers to accomplish this object, is not a subject of criticism.

This, however, is quite a different matter from the incorporation of a company with *general* powers to appropriate *all* the water supplies of a State, and to furnish more or less water from them to any places it may see fit to contract with for this purpose. It is very questionable if the purchase of the mill powers of a stream or the shores of a lake or pond by such a corporation entitles it to the absolute ownership of the water for any other purpose. In any case, it would certainly seem as if a city should have the same right of condemnation of water for its necessities against any such corporation or syndicate, as against any private parties, and that, moreover, it should not be compelled to pay any fancy price for it—any more, in fact, than the actual damage which its diversion may cause to manufacturing or riparian interests. Speculation in land, which, it is expected, a city or State may have to condemn for its own use, seems to be an unavoidable evil; but no good reason can be advanced why a private corporation, for the same speculative purposes, should be permitted to monopolize water supplies by granting it the same absolute ownership therein as in lands.

This question of the control and conservation of water supplies has been exciting a good deal of interest recently in the State of New Jersey, and Governor Abbett seems to fully appreciate its importance, as is indicated by his recent message to the Legislature.

Parasitic Chylocele in New Orleans.

The filaria sanguinis hominis is a curious parasite which has been proved to be the cause of chyluria, chylocele and elephantoid affections of the scrotum and lower extremities. These diseases are relatively common in the East Indies, and are met with in the West Indies and South America. Dr. John Guitéras, Dr. William Mastin, and Dr. De Saussure have also reported cases occurring in the South Atlantic and Gulf States, especially in Charleston, S. C. Dr. Rudolph Matas adds another case to the comparatively short list in a paper published in the *New Orleans Medical and Surgical Journal*, January, 1891. The case is interesting as an instance of accurate clinical diagnosis, subsequently confirmed by pathological study; but it also shows that the filarial diseases may in future become common in that part of the country. For while the patient was a native of Cuba, and in all probability became infected there, yet he had lived in New Orleans nine months before he came under observation for chylocele of the testicle. This fact of course proves that the climatic conditions of New Orleans, as those of Charleston, are well adapted to the development of the filaria. In Dr. Matas's case the embryos of the filaria were found in the chylous fluid from the testicle and also in the blood.

Dr. Matas reports his case with great care, and adds much to the value of his paper by giving a very interesting account of the first discovery of the filaria, its life history, and of the diseases caused by it, with a few re-

marks on prognosis and treatment. When the adult female parasite can not be discovered, and usually it can not, Dr. Matas thinks the most important therapeutic measure is removal to a cold climate and a high altitude. Such a radical change in the environment of the best gradually brings about the destruction of the parasites.

Relationship of the Diseases of Animals to those of Man.

The *Medical Press*, January 28, 1891, says: The discussions which have recently taken place as to the causation and prevention of tuberculosis, have invested with a peculiar interest the question of the relations of the diseases of the lower animals to those of man. The subject is one to which attention has not been long directed, but even at this early stage, it bids fair to add considerably to our knowledge in respect of the prophylaxis of certain transmissible diseases. The matter, as a whole, has been assigned a special section in the Congress of Hygiene which is to take place in London in August next, and the section will take into consideration, *inter alia*, the infectious, contagious, parasitic, and other diseases communicable from animals to man, and *vice versâ;* the methods of the propagation of diseases affecting mankind by means of animals and animal products; the infection of meat, milk and other comestibles; and the restrictions to be placed upon the sale of infected food and the movements of infected animals. On each of these questions papers will be obtained from the highest British and Continental authorities as the basis of the debates, which ought, therefore, to prove exceedingly instructive and interesting. Though less attractive, the prevention of tuberculosis and kindred diseases is vastly more important than their cure, and promises very much more satisfactory results.

Infectiousness of Croupous Pneumonia.

In the *Bolnitchnaia Gazeta Botkina*, No. 29, 1890, p. 714, Dr. Nil I. Sokoloff, senior house physician to the Alexandrovsky Pavilion Hospital, St. Petersburg, publishes a valuable paper in which he brings forward the following several propositions. 1. Croupous pneumonia represents, most undoubtedly, an infectious disease, which (in hospitals) spreads from man to man very much in the same way as erysipelas. 2. Patients suffering from typhoid, typhus and relapsing fevers manifest a quite peculiar predisposition to catch the infection. 3. The mortality amongst such patients contracting pneumonia is truly enormous (about 65 per cent.). 4. In view of the fact, all hospitals should be furnished with special wards for pneumonic patients. 5. As soon as a typhoid patient, when staying in the hospital, develops signs of pneumonia, he must be at once isolated, and the ward most strictly disinfected. 6. No ward which has been occupied by pneumonia cases can be subsequently used for other patients without a preceding thorough disinfection. 7. In view of a generally high mortality from pneumonia (amounting to 12 per cent. under best management of the cases); and of the infectiousness of the disease, the appearance of an epidemic of croupous pneumonia in the town given should always constitute an imperative indication for adopting strictest general sanitary measures. 8. Every one and all of hospitals should keep special isolation wards for admitting diagnostically obscure cases of infectious affections.

Hemoglobinuria from the Use of Quinine.

Dr. Coromilas, of Calamata, Greece, in the *Journal de Médecine*, January 25, 1891, reports six cases in which hemoglobinuria repeatedly followed the administration of quinine. None of the patients could take the sulphate, two could not take cinchona in any form, one not the salicylate, one not the valerianate, one not the hydrochlorate of quinine, without the occurrence of hemoglobinuria; while two could take cinchona, and one of these the salicylate of quinine also with safety.

Resolution.

Woman's Medical College of Pennsylvania.

Philadelphia, Pa.

Dean's Office, Feb. 21, 1891.

Resolved, that the Faculty of the Woman's Medical College of Pennsylvania approves of the present bill of Hon. Frank M. Riter to establish a State Board of Medical Examiners and Licensers.

WILLIAM R. WARNER & CO.'S

PIL. CHALYBEATE COMP.

IN THE TREATMENT OF

LA GRIPPE.

FORMULA:—Carb. Protoxide of Iron, gr. ijss.
Ext. Nux. Vom., ... gr. ⅛

ADVANTAGES:—Does not constipate, is easily absorbed, is nerve tonic and quickly soluble.

The effects left by La Grippe are marked Physical Prostration for which Pill Chalybeate Comp. (Warner & Co.'s) is almost a specific. The assimilable iron, acting as a blood tonic and the Nux Vomica as a stimulant to the spinal cord.

Dose, begin with one pill every four hours and increase to two pills three times a day.

The acute symptoms of La Grippe are controlled by (**EFF. ANTALGIC SALINE**), one dessert spoonful of which contains 4 grains Antipyrine and 4 grains Salicylate Soda. Physicians will not be disappointed in the treatment of La Grippe by trying this salt followed by PILL CHALYBEATE COMP. as above mentioned.

WILLIAM R. WARNER & CO.,

1228 MARKET STREET, PHILADELPHIA. 18 LIBERTY STREET, NEW YORK.

AVOID SUBSTITUTIONS AND SPECIFY WARNER & CO.

☞ The Coating of PILL CHALYBEATE CO. is Colored a Delicate Pink. ☜

The Model Ledger
enables a physician to make out his bills with great ease. Beside this, it tells at a glance just how much he has earned in any quarter; how much he has received; and how much is still due him. These are all good things for a doctor to know.

Specimen Pages will be sent on Application.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

Clinical Lecture.

MALIGNANT DISEASE OF THE PELVIS IN A GIRL UNDER FIFTEEN YEARS OF AGE.—OPERATION.[1]

BY WILLIAM GOODELL, M. D.,

PHILADELPHIA.

Gentlemen: To-day I have a case for operation. We have been preparing the instruments while the patient is being etherized. I have in this tray fifteen of the smaller hemostatic forceps and four of the larger. These numbers have been written down on a piece of paper. In addition, I have one knife, one teneculum, one grooved director, scissors, aneurism needle and a needle holder. These I do not put down, because they are invariably present, and they are not likely to get into the abdominal cavity. We have also marked down the number of sponges which we have. There are nine. It is very important to keep the record of these articles, for I have collected some thirty cases in which a sponge or a forceps has been left in the abdomen. I shall not soon forget the great distress and anxiety I had after an operation some years ago. I went into the country to perform an ovariotomy, and having no skilled assistant I had to supervise everything. I thought I had the number of sponges impressed upon my mind, but after the operation was over I had forgotten their number, and I was unable to say whether I had all the sponges or not. All that night on the train I was kept awake by my anxiety in regard to this point. I knew that when I got home I should be able to tell by the number of sponges which remained in their jar. On arriving, I was greatly relieved, indeed delighted, to find that I had them all. Since then, I always make it a point to write the number down.

Here is the patient, a girl not yet fifteen years of age. Last January she noticed that she was larger than she should be. Menstruation has gone on regularly. I happened to be in the town where she lived, to perform an abdominal section, and her physician asked me to see her. I examined the case carefully, and made up my mind that she had a tumor, which probably was malignant. Of course the question of pregnancy was not overlooked. I examined the breasts, vagina and cervix uteri carefully. I found the hymen present. But that would not exclude the idea of pregnancy; for there are many cases on record in which a hymen has been unruptured, with perhaps only a pin-hole opening, and yet pregnancy has occurred. Day before yesterday I examined her with the sound, and found the womb absolutely immovable. It is pushed against the pubic bone on the left side and flattened. The tumor comes into the vagina as far down as Douglas's pouch, so that I am afraid we have pelvic adhesions. It perhaps is an intra-ligamentary cyst that has formed between the layers of the broad ligament. Such a tumor as this cannot escape upward; and it grows downward, dissecting off the peritoneum from the pelvic cavity. In these cases of apparently firm fixation from adhesions, however, I have sometimes been agreeably disappointed. I have found that the tumor was retained in the pelvis simply by the suction from close contact with the pelvic walls. When boys, you have seen heavy stones lifted with a wet piece of round leather to which a string was attached. The wet leather is pressed upon the stone and is kept in firm contact with it by asmospheric pressure through the vacuum under the leather. This is sometimes the case with these tumors. They are held down in the pelvis by this kind of suction and not by

[1] Delivered at the Hospital of the University of Pennsylvania.

adhesions. Fearing, however, that we may meet with bad adhesions I have the Paquelin cautery ready, and have asked Dr. Taylor to supervise it. The abdomen has been thoroughly cleaned, and scrubbed, and washed with the antiseptic solution.

There is evident fluctuation in this tumor, which is irregular in shape. After estimating the thickness of the abdominal wall by grasping it between my fingers, I make the incision. I do this boldly, because I am sure that there are no intestines in front of the tumor. Reaching the recti muscles I search for the line of junction and at once come down upon the præ-peritoneal fat. Checking the bleeding with forceps, I raise the tissue with two other forceps, and open it by cutting between them. Then I come to another layer, which I catch up and incise in the same way. This opens the peritoneal cavity and exposes the tumor, which has the appearance of a malignant growth. As it is evident that we shall have bleeding, I enlarge the abdominal incision freely, in order to have working room. The walls of the tumor are extremely thin, and the least manipulation causes them to burst; and you see that the thick substance which is escaping resembles cerebral matter. To the upper portion the omentum is attached. This I separate and catch temporarily. Here is the left Fallopian tube spread out over the growth. As I try to turn out the tumor it breaks at every point. The growth involves the whole broad ligament, and it is very difficult to detach it. In order to get rid of the attachment of the omentum at the upper portion of the tumor, I tie it *en masse* and cut it off. I never met with a growth exactly like this before. The whole broad ligament is the seat of disease, and the bleeding is very free. The diseased mass is probably malignant, for it extends down deep into Douglas's *cul-de-sac*, and has attacked the pelvic walls so that it is impossible to remove it wholly. All that I can do is to check the alarming bleeding and remove as much of the growth as possible. It will be necessary to insert cobbler's stitches across the whole extent of the broad ligament. This I do, tying the stitches at short intervals. The womb also is implicated and it will have to be removed. This is done by transfixing the cervix, tying it on either side by a double ligature, cutting off the uterine body, and then sewing the edges of the stump to one another by gut sutures.

Considering the nature of this disease and its extensive ravages, it is surprising how little this girl has suffered.

As you see, her condition is a very serious one, for the shock has been great. Her pulse is extremely weak and there is great danger of her dying on the table. We have been giving her hypodermic injections of strychnia and digitalis. Had I known beforehand what would have to be encountered I should not have operated; but having begun, I was forced to continue. I irrigate the abdominal cavity thoroughly and insert a drainage-tube and close the abdomen. I have been fortunate in controlling the bleeding so easily. These are the cases in which it is sometimes necessary to pack the abdominal cavity with gauze and to leave it there for several days.

The whole back portion of the uterus has been eaten away by the disease. It looks as if gnawed by rats. The omentum, broad ligament and pelvic tissues are also involved. This is the first time that I have ever removed a womb by abdominal section for cancer of its body. I have extirpated the whole organ per vaginam, but that is altogether a different operation. The disease in this case probably began in the ovaries, for I came across a cyst which had the mother-of-pearl appearance found only in ovarian tumors. I performed the operation with all the ordinary care and precaution; but I do not see how it is possible for this girl to get well, although she may possibly recover from the operation. This, however, is even doubtful, for she has lost much blood and is fearfully collapsed, and may die in a few minutes.

You may ask me, Did I ever lose a patient on the table? Yes; I once had that misfortune. Some years ago I was called to a distant town to see a woman with cancer. While there, the physicians present told me that there was in the town a poor school teacher who had been bed-ridden for months, with obstinate constipation and vomiting, caused by the presence of an abdominal tumor. She was frightfully weak, and emaciated and bed-ridden. I found that she had two ovarian tumors, and also a bad stricture of the rectum. I promised that if the physicians would dilate the stricture and thereby get her into better shape, I would come and remove the tumors, although it was a very hazardous case, and that, in her weak condition, if the cysts were adherent she would most likely not recover from the operation. Well, after the

lapse of six or more weeks the physicians wrote to me that the vomiting had been checked to some extent, and that her general condition was better. I therefore went up and performed the operation, although she was still dreadfully weak. Only one of the gentlemen had ever seen an abdominal section before, and they all watched the operation with a great deal of interest, and I, not having a skilled assistant, was equally intent. The tumors were removed after a somewhat serious operation, and I was congratulating myself that everything had gone along so well, and had indeed begun to sew up the wound, when the physician who was giving ether said that the patient had stopped breathing. We tried in vain to resuscitate her. She was dead, and we were all greatly shocked. Then came up the question who should inform the family, and the two attending physicians begged me to do it. I broke the bad news as gently as I could, but it was a hard task, the hardest I ever undertook. In a small country town bad news travels fast, and when we left the house we were buttonholed at every corner and had to repeat the sad story over and over again. Naturally, I did not feel like remaining in the town any longer than was possible, but there was no train until evening; so I telegraphed to the main office of the railroad company and asked the head official to let an express train stop for me, early in the afternoon, which he was kind enough to do. But while waiting for it at the station, I had to go over the story again to some bystanders. One of the attending physicians was a man weighing some two hundred and fifty pounds. A few weeks after the operation his wife wrote to me, stating that her husband's health was failing, and she described his symptoms, which were those of diabetes. I told her to get some of his urine without his knowledge, and send it to me. This was examined and found to contain sugar. I therefore wrote to him, explaining what we had done, and advising him to consult a specialist. He did so, but got no better. Finally he went to a warmer part of the country and stayed there, struggling desperately to live, but he finally died. I believe that he had had a latent tendency to diabetes at the time of the operation, and that the shock of our patient's death developed it at once.

Some years ago a well-known English surgeon came to this country, apparently well. While in this country he received a terrible mental shock, and at once his health went down. Albumin, I think, was found in his case; but I am not sure whether it was albumin or sugar. He continued to fail, and that so rapidly that he died at sea while on his way home.

I do not recollect having had any other patient die on the table, but we have had some very close calls. The woman on whom I operated last Friday in the ward class came very near dying on the table. We had to stop twice during the operation, which was undertaken for the removal of a pus sac. The patient was greatly reduced and had a high temperature with a pulse of 130. After the operation the temperature came down, and since the operation it has not been over 99°.

I do not think that this girl will live over forty-eight hours, for in her condition, reduced as it is by a malignant tumor, she probably has not a sufficient amount of vitality to react. I shall at once begin to give her nourishment by the bowel, with small doses of whiskey by the mouth. I order whiskey, because we cannot nowadays get decent brandy. All the brandy in this country is a manufactured article. You can, however, get pure whiskey, if you pay enough for it. I shall give teaspoonful doses every fifteen minutes until reaction sets in. I put in at the lower angle of the wound a glass drainage-tube, and it will be examined every half hour. If there is bleeding, I shall inject a little diluted Monsel's solution. I have never had to resort to this styptic in this way, but it is a proper thing under certain circumstances. I have stitched the stump of the uterus to the lower angle of the wound. I use the drainage-tube, because with this malignant tissue in the pelvis we are almost certain to have septic trouble if the patient lives forty-eight hours. Whatever the result may be I shall inform you.

Two weeks later the patient was again brought before the class, and Dr. Goodell made the following remarks.

This is our patient of two weeks ago. She has gained in flesh and in color since the operation, and is, in fact, a great deal better than before it. The glass drainage-tube has been removed and has been replaced by a rubber one. To-day I wish to see if we can remove this. There has been considerable discharge. I shall also remove the stitches that secure the uterus to the lower angle of the wound. The reason that the drainage-tube has been kept in so long, is

the fear that the discharge from the diseased tissues left behind would set up septic trouble. I may be mistaken in regard to this being malignant disease, for she has improved far more than I should have expected. I have, however, repeatedly seen in cases of cancer of the breast, where the disease has been removed and a clean wound substituted for the large sloughing wound, great improvement follow. I have seen the same thing in cancer of the womb where, by removing the neck, or the womb itself, or by curetting, the patient will greatly improve, because the hemorrhage has been stopped and there has been removed temporarily, at least, the source of the chronic blood poisoning. After such an operation the appetite often improves wonderfully, the color comes to the cheeks and the patient and her friends may think that she is cured; but after a time the disease returns anew in the old locality or in adjacent organs. It will, therefore, not do to trust too much to the appearances of the patient. We shall now have her removed.

A gentleman has just handed me a note, in which he said that he and Dr. Formad examined portions of this growth and found it to be a round- and spindle-celled sarcoma. That leaves no doubt about it, and acting on this information I shall take out the drainage-tube and allow the wound to heal. For, if it heals up, the development of the growth will be inside and therefore unseen, instead of outside, through the opening.

I once learned a lesson in regard to this point. I removed a malignant growth and left the drainage-tube in a long time. The result was that at the reproduction of the disease it burst through the opening, making a horrible mess and stench. I do not think that it hastened the death of the patient, but it made everything unpleasant around her. Her friends, of course, attributed the bursting forth of the carcinoma to the operation, and, as they were ignorant people, it was almost impossible to make them understand the cause of the trouble.

PILLS OF IRON PROTOCHLORIDE.—In a paper read before the Edinburg Chemists' Assistants Association, Mr. John Finlay stated that the following combination yields satisfactory results, barring the size of the pills: Ferrous chloride, anhydrous, grs. 3; glycyrrhiza, gr. 1; extract of glycyrrhiza, gr. 1. To make one pill.

COMMUNICATIONS.

MEMBRANOUS CROUP.[1]

BY C. L. DODGE, M. D.,
KINGSTON, N. Y.

"The term pseudo-membranous laryngitis, laryngo-tracheitis, or true croup, is applied to a common and fatal disease, the essential anatomical character of which is inflammation of the larynx, or of the larynx and trachea, with the formation of a pseudo-membrane upon its surface."[2] A generation ago this was a common disease. It is occasionally met with at the present time, but most of the cases that we now see are, strictly speaking, laryngeal diphtheria.

Etiology.—It is now held by some of our highest authorities that membranous croup and laryngeal diphtheria are identical. Thus Northrup[3] tells us that "He believes it is not possible in the present state of our knowledge to separate purely local croupous laryngitis from laryngeal diphtheria of mild type," and that "it seems advisable, therefore, to consider all cases of pseudo-membranous laryngitis not of traumatic origin, as local manifestations of diphtheria, and base the treatment on that diagnosis." From this opinion I feel obliged to express my dissent. Jacobi also says:[4] "In former times which are unknown to the younger generation of physicians, when no such epidemics [of diphtheria] existed, the only form of diphtheria occurring now and then, was the local laryngeal diphtheria called pseudo-membranous croup. It was then a rare disease, while at the present time it is of but too frequent occurrence." This statement I regard as misleading. Membranous croup was *not* in former years so very rare. In 1858,[5] the year assigned by Jacobi as the time when diphtheria first made its appearance here—and I may add that but five cases of death from this disease were reported that year in New York—there were 478 deaths reported from membranous croup. In 1859 there were reported 622 deaths from membranous

---

[5] *Vide* article Membranous Croup, by J. Lewis Smith, *Transactions New York State Medical Association*, vol. i, p. 432.

croup, which exceeds by 127 the average number of deaths per year reported from diphtheria, from 1860 to 1873. If the membranous croup of those days was, as Jacobi asserts, nothing more or less than local laryngeal diphtheria, why was it not contagious? Why did the diphtheritic process invariably begin in the larynx and remain there? Why did the constitutional symptoms of diphtheria, the septic poisoning, the enlarged glands, etc., never appear? Why were none of the sequelæ of diphtheria ever observed? In short, if it was the poison of diphtheria that gave rise to the membranous croup of that time, how shall we explain the fact that it never gave rise to general diphtheria, but invariably manifested itself as a localized disease of the larynx? Northrup states that of the autopsy records of one hundred and fifty-one cases of laryngeal diphtheria, in only one case was the membrane found in the larynx *only*, and he further remarks[1] that "The melancholy fact that but one case had diphtheria of the larynx *only*, stands out as a grim reminder of the tendency of the lesion to invade the regions adjoining it above and below." In former years this "tendency of the lesion to invade the regions adjoining it above and below" was not observed. How shall we explain this if the disease was the same as we now see it?

If there was once a disease called pseudo-membranous laryngitis that was produced by other causes than the diphtheritic virus—which I think few will be disposed to deny—then there is now a pseudo-membranous laryngitis distinct from diphtheria. "It is well, therefore," as J. Lewis Smith forcibly remarks, "to briefly recall the evidences that croup in a certain proportion of cases results from causes other than diphtheria. The occurrence of croup in localities where diphtheria is unknown of course indicates the operation of some other agency than the dipththeritic poison." Therefore I maintain that, before diphtheria became epidemic or endemic in this country, there must have been some other cause for the membranous croup which prevailed at that time.

In this, as in most other diseases, there exists a predisposing and an exciting cause. The chief predisposing cause is heredity: the truth of this is beyond cavil. Croup, as the phrase goes, runs in certain families from generation to generation. This is as well known among the laity as the profession. The common exciting cause (exclusive of the diphtheritic form) is exposure to cold. Standing by an open window with insufficient clothing on a windy day, seems frequently to be the starting point of an attack of croup. This is the history in so many cases that the relation of cause and effect seems almost equivalent to a demonstration. It occurs most often between the ages of two and seven years. The anatomical conformation of the larynx in childhood, together with a peculiar susceptibility at this age, seem plausible reasons for its greater frequency in the young. One attack seems to predispose to others.

Symptoms.—In diphtheritic croup we usually find the symptoms characteristic of general diphtheria. In the majority of cases the membrane appears first in the throat, and from there descends into the larynx. It is held by some that in the so-called uncomplicated cases the membrane is confined to the larynx—starts there and stays there. This is possible but it must be exceedingly rare, for Northrup, who avows himself a unicist in this matter, is able to show but one case of this kind in his statistics. He gives the autopsy records of one hundred and fifty-one cases of laryngeal diphtheria, and states[1] that "in fifty-eight cases diphtheria of the pharynx antedated the laryngeal symptoms, and in nearly all other cases, the number not being determined, membrane appeared sooner or later in the pharynx. In eighty-eight cases there was evidence that the membrane made its appearance first in the larynx, or at the same time as in the pharynx. *In only one case was it in the larynx only.*" The admission, "or at the same time as in the pharynx," robs this statement of much of its value as evidence that the laryngeal affection was the primary one. When true diphtheritic membrane appears in the throat the question of diagnosis is settled once and for all.

I wish to remark here that the classical description of croup, as well as of some other diseases, notably typhoid fever, is no longer to be trusted as absolutely correct. The truth of this statement will be made apparent as we proceed with the symptomatology.

Case 1. This occurred in my own family. Boy, two years and three months old, was taken suddenly about 12 o'clock Monday night, December 20, 1886, with a harsh,

[1] *Loc. cit.*, p. 528.

[1] *Loc. cit.*, p. 525.

croupy cough, slight fever and dyspnœa. I gave him small doses of syrup of ipecac and paregoric, and in less than an hour the attack passed over and he fell asleep and slept till morning. I considered the case one of spasmodic croup, and felt no uneasiness regarding it. It is proper to state also, in this connection, that the child had suffered the previous week from a cold and a slight sore throat—with no symptoms of diphtheria, however,—and had so far recovered that no treatment was required for a day or two before the attack of croup. The next day, December 21, he seemed better, but not entirely well. The pulse was slightly accelerated, but the temperature was normal. Towards night slight hoarseness appeared, but the child was up and dressed, playing around the room. On the 22d, the patient grew worse: he could no longer speak clearly and distinctly, and the peculiar nervous symptoms began to manifest themselves, still no fever appeared, the temperature was taken regularly and it remained normal throughout; the pulse was somewhat increased in frequency; the dyspnœa gradually increased, cough became hoarse, not harsh as in the beginning; voice steadily grew weaker. The throat was normal, frequent and thorough examinations showed no membrane or patches *at any time*. On Friday morning, the 23d, dyspnœa became the prominent symptom, attacks of suffocation came on, cyanosis increased till the lips became blue, and the fingers and face dusky. About six P. M. tracheotomy was performed, without an anæsthetic, as the child was semi-unconscious. The operation was rapidly and skilfully done, the child began to breathe naturally as soon as the tube was inserted, and in a few minutes took a drink of water. He slept well all that night, the tube required cleaning but few times till morning, when it began to clog badly. The false membrane descended into the bronchi, and the child died from suffocation at 1 o'clock Sunday. I deceived myself in this case by supposing—as I had been taught to do—that because there was no fever there was no inflammation, and, logically, if there was no inflammation there could be no exudation with false membrane. I now know what I did not know then, that the formation of false membrane in the larynx in some cases at least takes place without fever.

There were no cases of diphtheria in the neighborhood, the child had not been exposed to that disease, and no case occurred afterwards among any of those who were with him. On two occasions, when the tube became stopped up and the little fellow seemed on the point of suffocation I applied my lips to the tube and cleared it by suction. If the case had been one of diphtheria I certainly would have contracted the disease.

Furthermore, three other physicians of large experience saw the case and there never was any question as to the diagnosis. The medical treatment was the routine one of calomel, potassium chloride, emetics, alkalies, fumigations, etc.

Croup commonly begins gradually and insidiously, but there are many exceptions to this rule. The so-called prodromic symptoms are by no means invariably present. These symptoms, upon which great stress has been laid by some writers, consist of slight cough, with the other evidences of nasal, pharyngeal and laryngeal catarrh, with perhaps slight fever, although this is often so slight as not to be detected unless special attention be directed to this symptom. This condition may last two or three days or a week in some cases before the attack of croup is ushered in. This usually takes place in the night somewhere between nine and twelve o'clock, when the child is suddenly roused from his sleep with a loud ringing cough. At first it is short and sharp, but it soon becomes hoarse, and gradually grows weaker and less barking. The voice is also changed; it is hoarse and whispering, and gradually grows weaker and fainter as the disease advances, until it becomes wholly suppressed. The characteristic croupy respiration is present from the onset. Gradually inspiration becomes stridulous. At first expiration is short and harsh, later on it becomes stridulous also. The breathing now becomes somewhat quickened and symptoms of nervousness and extreme restlessness appear. The dyspnœa steadily increases, with occasional attacks of suffocation, from which the little patient emerges to struggle on a little longer. Inspiratory recessions now take place at the supra-sternal notch and the supra-clavicular regions. The soft parts also yield at the epigastrium. Cyanosis now comes on, the blood is no longer fully aerated and the lips become blue, the fingers and face dusky. Death takes place from strangulation, sometimes ending in convulsions and stupor.

Diagnosis.—The diagnosis of membranous croup from laryngeal diphtheria presents no difficulties when the latter occurs as a

complication of general diphtheria; it is only in those cases where the diphtheritic inflammation manifests itself exclusively in the larynx that we feel doubtful as to its true nature. Is it possible, then, to distinguish pseudo-membranous croup from laryngeal diphtheria? I believe that it is in some cases, but not always. If a child have croup after exposure to diphtheria, but with no symptoms of that disease, further than the laryngeal disorder, we are warranted in calling it diphtheritic: further, if a child die with croup without *known* exposure, and with no other symptoms of diphtheria, and shortly after other members of the family are attacked with unequivocal symptoms of diphtheria, we are also warranted in believing the first to be diphtheritic; but, *per contra,* if a child have a similar attack of croup and no other member of the family suffer, there being no history of exposure, and no epidemic prevailing in the immediate locality, I believe we are warranted in excluding the diphtheritic virus as the cause of the croup. The case cited above illustrates this point.

The points, then, in favor of diphtheria, are known exposure to this disease, or prevalence of an epidemic; albumin in the urine; prodromic symptoms adynamic. If favor of croup: lack of exposure, no epidemic prevailing; no albumin in the urine; prodromic symptoms not adynamic.

The ablest practitioners, however, admit the impossibility of making a positive diagnosis in all cases.

It is sometimes quite difficult to distinguish between membranous and catarrhal croup. Membranous croup usually begins gradually, although there are exceptions to this rule as illustrated in the case reported above. Spasmodic croup, that is, the attack proper, invariably comes on suddenly and unexpectedly, and in the great majority of cases in the night.

The severe symptoms of membranous laryngitis may first appear in the daytime. The pulse is of no value in the diagnosis; the excitement occasioned by an attack renders it absolutely worthless as an indication of fever *per se.* The temperature, on the contrary, is of the utmost importance, and should always be taken. The fever, in my opinion, is the most important symptom in the diagnosis. The older writers all tell us that membranous croup is attended with fever, and that in spasmodic croup it is mostly absent. This is one of the points in the differential diagnosis. In support of this statement I quote from Niemeyer who is usually very accurate in his descriptions. He says,[1] of the diagnosis, that "dyspnœa is rare in laryngeal catarrh, and is never persistent, nor is there much fever, while in croup, fever never fails." Now, as a matter of fact, this statement is almost exactly the reverse of the truth. To Dr. Jacobi belongs the credit of setting the profession right in this matter. He tells us, in positive terms, that catarrhal laryngitis in the child is a febrile disease. He also says[2] that uncomplicated sporadic croup has no increase of temperature or very little; catarrhal laryngitis is mostly attended with high fever. In very many cases this symptom has guided him safely, in spite of the statements of the books. "There is no fever or very little except in the cases of generalized diphtheria." My experience confirms this view. A case of croup developing suddenly at night, with high fever and flushed face, is almost surely catarrhal. Furthermore, in catarrhal laryngitis, the hoarseness (aphonia) and harsh croupy cough come on abruptly, and often subside in an hour or less, although in some cases the attack may last much longer—but sooner or later comes a decided remission. The child is pretty certain, however, to have a fresh attack the following night, just as sudden as the first. Neither the frequency of relapses nor the history of previous attacks of catarrhal laryngitis warrant us in assuming the catarrhal nature of an individual case, for quite frequently we meet with cases of true membranous croup in children who have experienced many attacks of catarrhal laryngitis.

Age also has some bearing on the diagnosis. Membranous croup is rare under one year, while, according to Jacobi,[3] twenty per cent. of all the cases of spasmodic croup met with are under one year.

When laryngitis is the principal element in the attack, hoarseness may remain for several days, but this of itself does not signify much. The totality of the symptoms, as the homœopaths say, is of great importance in discriminating between catarrhal and membranous croup. "In the latter," as Jacobi[4] ably maintains, "the main symptoms—viz., stenosis, hoarseness (or aphonia)

[4] *Loc. cit.*, p. 95.

and cough—will mostly develop simultaneously and in equal proportion; the unproportionality of the symptoms—for instance, much stenosis and cough, but little hoarseness, or barking cough and hoarseness with little stenosis—would speak for catarrh." Laryngismus stridulus is made synonymous with spasmodic croup by some writers. This is much to be regretted, as it tends to needless confusion. Membranous croup is easily distinguished from this affection. Laryngismus stridulus is not inflammatory, but purely spasmodic. It is attended with great dyspnœa or momentary suspension of respiration, without fever or cough. Furthermore, laryngismus stridulus is a rare disease in this country as compared with either catarrhal or membranous croup.

Prognosis.—The prognosis is unfavorable in the mildest cases. Diphtheritic croup has been said to be the most fatal disease to which childhood is exposed, and true membranous croup in infants and young children is equally fatal. The rate of mortality is very high. Authorities differ widely as to percentage: some, as Jacobi[1] and Mackenzie,[2] set the death-rate, without operation, at ninety per cent. On the other hand, J. Lewis Smith,[3] Meigs and Pepper[4] and Agnew,[5] believe that recovery without operation is more frequent than has commonly been supposed. According to Lovett and Munro,[6] the experience at the City Hospital (Boston) has been as follows: forty cases of diphtheritic croup have been treated medically and every one died. Dr. G. W. Gay, visiting surgeon, wrote, in 1885:[7] "Not a single case of pseudo-membranous laryngitis ever recovered in this hospital without operation." And he quoted Dr. D. W. Cheever, senior visiting surgeon, as writing to him in 1884:[8] "After reflection, I cannot recall a case of membranous laryngitis that I have known to recover without tracheotomy." Since Dr. Gay's article was written there have been two recoveries from moderate dyspnœa without operation. I have seen one case of diphtheria with croup as a complication—where the voice was faint and husky, with decided dyspnœa, in a girl five years of age—recover with medicinal treatment alone. I have also met with one case of membranous croup—judging from the almost complete extinction of voice, which at first was hoarse and feeble, together with the dyspnœa—in a girl six years old, which recovered without tracheotomy.

In diphtheritic croup much depends on the type of the epidemic. When laryngeal symptoms appear early, the attack is apt to be more severe than when they occur in the declining stages. The younger the age the higher the mortality; for the younger the child the smaller the windpipe and larynx, and the sooner stenosis results. Unfavorable symptoms are increasing debility and cyanosis, feeble and irregular pulse; also the development of bronchitis or bronchopneumonia. When emetics fail to act, or spontaneous emesis takes place, the case is generally hopeless. Among the favorable indications may be mentioned loosening of the cough, increase of expectoration and freer respiration.

Treatment.—The medical treatment of the present day is practically the treatment for diphtheria, since that disease is responsible for a large proportion of the cases of croup. The use of mercurials is advocated in all forms of membranous laryngitis. The bichloride of mercury is the preparation advised by most writers in as large doses as are warranted in each particular case. From one-sixth to one grain, in divided doses well diluted, is given during the twenty-four hours. Calomel is preferred by some as being just as efficacious and safer. The tincture of the chloride of iron is still a favorite with many practitioners. Potassium chlorate is condemned by most modern authors as being injurious to the kidneys. Formerly alkalies were much employed in the treatment of croup, for their supposed solvent action on fibrin (antiplastics of the older writers). Now, however, except in the form of inhalations with the atomizer, they are rarely prescribed. In diphtheritic croup I have obtained the best results from sulphur applied topically by insufflation and administered internally in small doses frequently repeated.

Unfortunately but few cases yield to medicinal treatment. Nothing then remains but resort to surgical measures.

We now have the choice of tracheotomy or intubation. The proportion of recoveries

after tracheotomy, according to Wharton,[1] is about one in every four cases. Intubation gives about the same, Waxham[2] placing it at 26.77 per cent.

MEDICAL JURISPRUDENCE OF RAILWAY SURGERY.

BY HAROLD N. MOYER, M. D.,

CHICAGO, ILLINOIS.

PROFESSOR OF PHYSIOLOGY IN RUSH MEDICAL COLLEGE.

When a suit is brought, the railway surgeon, according to my observation, is placed at a disadvantage in two ways; first, his testimony as an expert is always lessened in its effect by the question, "Are you an employee of the road?" Then again his loyalty to his principals, and his not infrequent detection of malingerers, place him in an attitude of "expectant attention," and he sees in every claimant not presenting palpable deformities a fraud and cheat. That this picture is not overdrawn will be apparent to most physicians who have devoted special attention to the practice of medical jurisprudence, and that it is one frequently accompanied by a large verdict for the plaintiff is a common experience. The railway surgeon should, I think, assume in all these cases that the person is injured and by demonstration and reasoning convince himself to the contrary if the facts warrant it. It has always been my custom when acting for the plaintiff in such cases to assume that the person was not injured and then by a chain of reasoning or direct observation to convince myself if possible of the contrary. I have so far always been able to make such conclusions effective on the witness stand. The human mind is so constituted that we cannot be too careful in eliminating unconscious bias, which at times may be apparent to every individual in a croweded court room, excepting its unfortunate but honest possessor.

The qualifications that a railway surgeon should possess have enormously augmented within a few years. It is but a short time since anatomy, operative surgery, and a modicum of pathology was about all that was needed. In too many instances the older railway surgeons have not advanced beyond this, and appointments are still made upon these lines. There never was a time in which extensive knowledge of pathology and internal medicine was more needed by the railway surgeon. It is precisely upon these lines that I have seen the most unfortunate results, in that the decision of the railway surgeon enforced a long litigation upon the plaintiff and usually resulted in the railway company paying a sum vastly in excess of what the case could have been settled for originally. In the majority of cases a meritorious case can be settled for much less than will be awarded by the average jury and the plaintiff will be saved vexatious litigation.

It is apparent that injuries which cause gross visible defects will never form any considerable part of this kind of litigation. The loss of a hand, leg or eye will and must always be measured in damages by the jury. The cases in which the judgment will turn on expert opinion will be those in which the injuries are obscure, to internal organs or deep-seated joints, in which the conditions must be inferred from objective and subjective symptoms; those in which the clinical picture will be the guide in reaching a diagnosis. Injuries to the nervous system will far outnumber those of other tissues and organs, and in the difficulty of their medico-legal diagnosis (to coin a phrase). It is in this class of cases that the railway surgeon seems to be most deficient. So-called spinal concussion has furnished a fruitful field of contention in railway medical circles and the deliverances upon this subject has not been altogether what could have been hoped for scientifically. It is not surprising when a railway surgeon is invited to meet a colleague in an examination to have the former request the patient to bend the body, stand upon one leg, balance his body with the eyes closed; then to percuss the spine, tap the patellar-tendon and announce that the examination is closed. When a surgeon who is accustomed to this kind of work has a deliverance upon spinal concussion, is it matter for wonder that the medical world is not impressed? So far as my own experience extends I have never met a railway surgeon at one of these examinations who was provided with an ophthalmoscope or an electric battery, nor have I seen a complete examination of the sensibility or of the reflexes made by a railway surgeon even when every opportunity was given.

The necessity of the railway surgeon being an "all round" man in the best sense

[1] *Keating's Cyclopædia*, vol. ii, p. 544.
[2] Quoted by Northrup. *Ibid.*

of the word is now more than ever apparent. Within a few years the testimony of experts consisted in stating his experience, qualifications, knowledge and opinion of the particular case. Now he is called upon to defend this opinion in the face of a cross-examiner, who may be equally or even better posted on the exact points at issue than he is himself.

It is a matter of experience that suits against corporations for personal injuries have increased greatly in the last few years and the amounts recovered have been much greater. This I think is due to two principal causes: the rulings of courts on the law of negligence, and the fact that corporations have too frequently fought cases in which both law and facts were against them, relying largely upon brilliant and well-paid counsel to tire litigants and defeat a meritorious claim. This condition of affairs has produced lawyers who practice this branch of the law almost exclusively, and it is now possible for litigants to secure the best of legal and medical talent by assigning a certain portion of the prospective judgment. It has been my experience that these cases are usually much better prepared, so far as the medical questions are concerned, for the prosecution than for the defense. Part of this preparation consists in posting the counsel on the direct points at issue and thoroughly indoctrinating him with the theory of the case adopted by the medical witnesses.

Cases are frequently injured—and this occurs about as often for the plaintiff as for the defendant—by calling a witness who writes M. D. after his name and whose opinion is adverse to the other side, while in fact he cannot sustain the opinion or himself on cross-examination. A recent case occurring in the city of Chicago in which a verdict of $30,000 was returned against a railway company well illustrates this point and shows the injury that may be done to a case by a poor expert witness. The plaintiffs put three physicians on the stand and the defendant company five. One of the latter, after airing his erudition on the joints, ligaments and muscles of the spine (the injury was to the spine), failed to remember what muscles were attached to the styloid process of the temporal bone. Another said that the spinal cord terminated opposite the last dorsal vertebra in the "caudal appendix." A third, when asked to give the normal order of the polar muscle reactions, said that he had never heard of such a thing and that the question was absurd and unanswerable. It must be apparent that such witnesses materially lessened the effect of the two remaining good witnesses and far outweighed the mere *ex cathedra* opinion of a larger number. Such witnesses are only an embarrassment and not a help.

Proficiency in clinical and operative surgery will for obvious reasons furnish the chief recommendation of the railway surgeon of the future, yet in my judgment they do not furnish the best training for the medical jurist. That is almost a separate branch of study, and requires a thorough kuowledge of physicial diagnosis, not only surgical but medical and also pathology. The medical jurist should perfect himself in all the most improved methods of diagnosis, in all branches of medicine, more especially those methods which furnish us with the objective signs of disease, for after all it is the objective signs that determine the status of a case in court. To these should be added a careful study of the art of medical jurisprudence—that is, the orderly presentation of facts and theories, so as to lead up to a logical conclusion and all that in plain, non-technical language and in such fashion as to convince the average juryman that his position and judgment are unassailable.

TRAUMATIC NEUROSIS.—TEMPORARY INSANITY FOLLOWING OPERATION FOR ABSCESS.

BY WILLIAM H. SHIPPS, M. D.,

BORDENTOWN, N. J.

On April 2, 1890, I was requested by a fellow-practitioner, to operate upon a patient suffering with a large abscess, situated in the upper portion of the right breast and extending to the axilla of the same side. The patient, a man 40 years of age, stated that the abscess was the result of an injury sustained a month before, and had been gradually developing ever since, causing him intense suffering. He had been under the care of two physicians, who had used both local and internal treatment with the hope of aborting the abscess. There was nothing about the general appearance of the man to attract notice, except, perhaps, a certain dulness of expression, and a quick, nervous manner of speech, which at the time I attributed to individual peculiarity. He

gave me a brief account of the injury and the treatment employed, and denied ever having been the subject of specific disease. Without further ceremony I freely opened the swelling, evacuating about eight ounces of pus and blood, after which an antiseptic dressing was applied. Immediately the patient expressed himself as much relieved, and stated his intention of at once returning home by rail, a distance of ten miles. From this, however, he was dissuaded, and urged to pass the night at a friend's house in this city, in order that opportunity might be given me to re-dress the parts in the morning.

The morning following, I called upon the patient, and was surprised to learn that, shortly after entering his friend's house, he had begun to talk and act strangely, altogether unlike anything which had been known of him before. During the night he became at times unmanageable, refusing to go to bed or take either medicine or nourishment. On entering his room I found him before the mirror, gazing vacantly at his image in the glass. He was almost naked, and had torn every vestige of the dressing from his body. He seemed entirely indifferent to the presence of others about him, save that our entrance caused him more or less uneasiness, which was evidenced by his continually pacing the room and peering out of door and window, as if in search of some avenue of escape. On motioning him to a chair, he would insist upon getting on it with his feet, repeating the operation as often as I attempted to make him occupy it in the natural position. At times he would insist upon getting out of the windows, and was only prevented from so doing by the determined resistance of his attendants. For two days he absolutely refused all food, and during that period had not slept an hour. His pulse and temperature being normal throughout, and careful inquiry of friends and relatives as to his family history throwing no light upon his present condition, I felt no hesitancy in pronouncing the case one of temporary insanity. I therefore advised that he be removed as speedily as possible to the State asylum for the insane. In this I was seconded by Dr. I. D. Young, of Bordentown, who very kindly saw the patient with me. Accordingly arrangements were made for the patient's removal the day following, or the third day after the case came under my observation. Early in the morning of the day fixed for his departure, I called at the house for the purpose of facilitating his removal. On entering the dwelling, I was met at the door by his host, who with smiling countenance informed me that "John was all right now." On inquiry I ascertained that shortly after midnight he had fallen asleep for the first time in three days, sleeping soundly until daybreak, when he awoke perfectly calm and rational. On meeting the patient I was happy in being able to confirm all that had been told me, and found him sitting up apparently clothed in his right mind, sensible that something was amiss, but totally ignorant of the nature of his attack. In a day or two he returned home, unaccompanied, and since then has been in the enjoyment of good health.

The case was doubly interesting to me, because of the unexpected sequela of the operation, and secondly because his friends attributed his insanity solely to the operation, arguing that as the man was sane prior to the use of the knife, and insane almost immediately afterwards, but one conclusion could be drawn. The satisfactory termination of the case, however, quickly put to flight all such nonsensical reasoning as this.[1]

Foreign Correspondence.

BERLIN LETTER.

The Latest Developments in the Tuberculine Question—Koch Worried and Intimidated.—The Position of the Government in the Case.—Voices from Hospitals.—Vox Populi.—Professional Feeling in the matter.

BERLIN, February 17, 1891.

The storm of enthusiasm has passed and the low tide of cold inspection and calculation has set in. The miracle is—not what little there is left of the glowing anticipations of the Koch Chauvinists, but that there is anything left at all. It required the stern and pitiless voice of Virchow to restore to the profession the common sense which apparently had been completely lost. It required, moreover, unwarrantable sacrifices of human lives to convince the profession that the millennium of medicine has not yet

[1] [Neuroses following surgical injuries and operations have of late attracted considerable attention, and this report by Dr. Shipps is an interesting contribution to the subject.—ED. REPORTER.]

arrived. Virchow, as I have learnt from a good source, will continue his warfare against the "lymph" without zeal or malice, but with a persistence which will ultimately prove fatal to the young remedy. As to the deaths caused by tuberculine, I regret to state that their number is not a small one. Sudden failure of vital energy caused by the artificial fever, hemoptysis, and miliary tuberculosis are the chief sources of danger from the exhibition of the remedy. Quite recently a young medical man who had contracted a catarrh of the apex was hurried to death by a rapidly developing miliary tuberculosis under the influence of tuberculine.

Koch's path during the last two months was not a rosy one. His private residence in the Thiergarten, formerly an ideal of seclusion and privacy, soon became the centre of attraction. In spite of all possible signs and inscriptions, such as "moved out of town," postmen and telegraph messengers vied with patients and doctors in besieging the house. He actually did move temporarily to a friend's house, but was hunted and found out by two Western practitioners. There was nothing left for Koch but to flee. Those anxious to see him can do so at Luxor or Ghizeh, near the pyramids which are fortunately unable to interview the German doctor. Koch's flight had, besides, another reason, viz., the gradual falling off of his admirers and the steady increase of his opposers. It is rumored that he left worried and full of anxiety.

In a still worse fix, however, than Koch, is the German Government, and especially von Gossler, the Cultus Minister. It is undeniable that von Gossler alone has brought about the present unpleasant state of affairs in the matter. Koch yielded unwillingly to that official's incessant demands to publish a matter as yet unfinished. Von Gossler evidently was led by political and national impulses. The question of emoluments for the Koch cause has of late changed its aspects. It is likely that no financial aid will be extended to Koch personally. As the matter stands at present, it is more than doubtful whether the Reichstag would vote a large money-grant for the purpose. Meanwhile authoritative voices of clinicians continue to take stand against tuberculine. The Berliner Jüdische Krankenhaus has had a sad experience with the new remedy, and Prof. James Israel, its famous Chief, has banished it completely from the wards. I listened last night to what Sanitätsrath Dr. Thorner had to say about tuberculine before the Verein für Innere Medizin. He had used the remedy since November 20, last year. Thorner censured severely the present arrangement in the distribution of the remedy, which secured for some hospitals and a few clinicians an actual monopoly of the remedy. The ordinary practitioner, he said, ought by all means to be able to obtain the remedy, for he can detect the signs of initial consumption before even the patient himself is aware of the affection. Thorner has had quite satisfactory results with tuberculine, though in one instance the remedy killed a patient. In the majority of cases a considerable improvement took place, as evidenced by a decrease of subjective difficulties and increase of bodily weight. In one patient suffering from apical catarrh, the bacilli had left the sputa under the influence of tuberculine. Thorner then communicated some interesting observations he had made in experimenting with the remedy upon animals. Any animal, he said, suffering from miliary tuberculosis can be cured with tuberculine. This statement—being absolutely new—created considerable astonishment. Likewise interesting was Thorner's statement that, as long as an animal was subjected to tuberculine injections it was immune against infection of tubercle bacilli, and that this state of immunity ceased as soon as the tuberculine was withdrawn. Hence it is clear that Koch's remedy can never be utilized as an immunization lymph against tuberculosis.

There are authorities like Prof Schroetter of Vienna—one of the consulting physicians of the late Emperor Frederick, at San Remo—who deny not only the therapeutic but also the diagnostic value of tuberculine. Bardeleben and Bergmann have lowered their enthusiasm to a minimum, while Leyden and Gerhardt still believe in its future. Henoch, the Nestor of pediatrics, has in plain words designated the remedy as useless and dangerous for children.

Possibly it will interest you also to learn what the Berlin populace think at present of the remedy. The common feeling is very much opposed to the Koch cure, and it is not too much to say that today no intelligent Berliner would submit to its exhibition on his own person.

The profession too, on the whole, is antagonistic to the Koch cure. The Berlin Medical Union at Friedrichstadt, has just formulated its disapproval of tuberculine and

is determined to take a firm stand against the remedy and especially against the present mode of its distribution.

PERISCOPE.

Tachycardia Cured with Electricity and Belladonna.

Dr. Thomas Oliver, Physician to the Royal Infirmary, Newcastle-upon-Tyne, says in the *British Medical Journal*, January 31, 1891:

In July, 1890, I was asked by Dr. Farquharson, of Newcastle, to see with him in consultation a young man, aged 28—a nervous, anxious-looking and emaciated man, who was slightly cyanosed. There was no history of rheumatism. Five or six years ago he met with an accident, and again, two years ago, when he fell over a "tipping" with his horse and cart. Though not materially injured at the time, he felt as if he had had a shock. From this date he became extremely nervous, and began to lose all his energy and pluck; he became afraid even of his own horse. He now began to suffer from attacks of violent palpitation, which would last for several days, and within the last three months he has been seldom free from these attacks of palpitation and a sense of cardiac distress for more than a week at a time.

When seen first by Dr. Farquharson in these attacks, the pulse-rate was generally from 190 to 230 in the minute. In his quiet state the pulse seldom exceeded 90, and when this was the case there could be heard a well-marked mitral systolic murmur. There was no albuminuria, no distended jugular veins, and no œdema of feet, but the left pupil was noticed to be smaller than the right—a condition of things which became more pronounced, Dr. Farquharson stated, if the stomach were distended with flatus. He had lately been the subject of dyspepsia and constipation and when these were present his cardiac distress was increased. Beyond a sense of discomfort, of præcordial pain and uneasiness which the excited action of the heart caused, there was no marked dyspnœa. His sleep was broken and fitful. By his illness he had been rendered quite unfit for work.

The slight cyanosis alluded to was noticed in the lips, on the face and in the finger ends. The pulse was small and extremely rapid. I counted up to 240 beats in the minute and then lost it. It was upwards of 250 on Dr. Farquharson's reckoning, but on this point we speak guardedly. Knee-jerks were slightly exaggerated. The lungs were perfectly healthy. Heart: the apex beat, which was very diffused, was felt two inches external to the nipple; there was also marked epigastric pulsation; pulsation, too, was seen and felt to the right of the sternum at the level of the right ventricle. The area of cardiac dulness was increased transversely. The tap of the heart could be seen and heard quite distinctly several inches from the chest—I thought about two feet. Over the aortic area—extending up to the episternal notch and down the sternum to the xiphoid cartilage—was heard a rough grating systolic murmur, followed by a well-marked second sound. It was only by counting the loud second sound of the heart that we were able to estimate the rate of cardiac pulsation. In addition to the grating systolic murmur mentioned above, a soft mitral systolic could be heard, which was carried towards the left axilla, and particularly towards the back at the level of the fifth dorsal spine. Pressure upon the pneumogastric nerve in the neck slowed the action of the heart. The urine was normal; the internal organs of the abdomen appeared to be healthy.

We arranged that he should have 30-minim doses of tinct. belladonnæ, with small doses of Fowler's solution; that for a few days the ether spray should be applied to the back of the neck, and afterwards the interrupted current to the pneumogastric, one pole behind the neck high up, and the other along the course of the nerve in the neck. Within a fortnight he was very much better. His pulse was never higher than 120 a minute, and that only during excitement. A sphygmographic tracing taken at this time showed low arterial tension and well-marked dicrotism. There was still the well-marked pericardial grating and mitral systolic murmur. The area of cardiac dulness remained as before; in its lateral diameter it measured 6½ inches.

It is now seven months since I saw him, and Dr. Farquharson tells me that the patient has made an excellent recovery. Only once since the beginning of July has there been a return of the very rapid action of the heart, and on that occasion it only lasted two or three hours instead of the three or four days as previously. His pulse

at present is never higher than 80 in the minute. For the last few weeks he has been taking arsenic and digitalis.

From being an anxious-looking, irritable and nervous man, unable to follow his employment, he has become calm and more self-possessed, and is now able to carry on his employment, not so much in the out-door department as in looking after the financial concerns of the business. The only unpleasant symptom which has been left is something akin to agoraphobia. In coming into Newcastle by road or rail he has to cross the High Level Bridge which spans the river Tyne, and whether he is in the train or on the roadway he always experiences, when on this bridge, unpleasant sensations originating at "the pit of the stomach as if a void had been suddenly created." This is so apt to be followed by increased rapidity of the heart that knowledge of this fact prevents him from making the journey into Newcastle as frequently as he would.

The subject of tachycardia has attracted considerable attention since Dr. Samuel West and Dr. Sansom have written upon it, and latterly our interest in it has been revived by the remarks made by Sir Dyce Duckworth in the discussion which he opened at the Birmingham meeting of the British Medical Association on Functional Disorders of the Heart. In the absence of a rheumatic history, the origin of the disorder in our patient must be sought for in some condition of the central nervous system induced by the fright and shock, although the pericardial grating, the mitral systolic murmur and enlargement of the heart—in the absence of any pronounced vascular lesion, such as aneurism—must not be lost sight of. The immediate effect noticed when gentle pressure was applied to the pneumogastric nerves in the neck, and the good result which followed electrical stimulation, point in the main to a central cause suspending the inhibitory action of these nerves upon the heart, or to increased activity of the accelerating branches of the sympathetic.

Suppuration of the Antrum of Highmore.

In the *Indiana Medical Journal*, Febuary, 1891, Dr. L. C. Cline, of Indianapolis, has an interesting paper on suppurative disease of the antrum of Highmore, in which he says: The antrum, owing to its size, situation and its relation to the nasal cavities and the teeth, is more frequently involved in the suppurating process than any other of the cavities of the bones of the face and skull which communicate with the nasal passages.

This cavity becomes involved principally from two sources, namely, dental complications and hypertrophic rhinitis. The inflammation does not extend into the antrum by continuity, but probably by the hypertrophy and turgescence of the nasal membrane producing stenosis or complete occlusion of the opening, thus causing hyperemia of the mucous membrane of the antrum, resulting necessarily in an increase of secretion, which accumulates and eventually degenerates and causes a purulent discharge; for it is generally conceded that a catarrhal secretion in a closed cavity will, sooner or later, give rise to a discharge of pus. The symptoms of an acute or recent case are pain and tenderness, with a sense of weight and fulness over the antrum and a pressure up against the eye, with slight hyperemia of the ocular conjunctiva. If due to dental origin, there will be slight pain on pressure of the corresponding teeth. When due to occlusion of the orifice from swelling of the turbinates, there is nearly always severe neuralgic pains, accompanied by more or less swelling and tenderness of the face in the region of the antrum. The pain is usually worse in the morning, and will be increased by stooping or lowering the head. The formation of pus is announced with a chill followed with fever, and if the closing of the opening of the antrum be due to turgescence or swelling of the turbinate bodies from cold, the symptoms may all subside in a few days, and the inflamed membrane will return to its normal condition, or the purulent discharge may continue in a less quantity indefinitely and all the acute and painful symptoms subside.

If the opening of the antrum with the nasal cavity remain free, as in the case of dental origin, the pus finds its way through the opening, and may produce by its constant irritation an obstinate turgescence of the turbinate bodies and occlusion of the nasal passages. The pus is usually discharged at intervals during the day, viz., on rising in the morning and in the afternoon, and when stooping. It is thought by some that when the pus has a dental origin, it is more offensive than when it is due to colds.

The diagnosis is not difficult, as a rule, in the recent or acute cases. The history,

coupled with pain referable to the antrum and side of the face, together with the discharge from one side, will determine the diagnosis. If the case is chronic, a careful inspection of the nose will result in finding pus on the anterior and inferior part of the middle turbinated body; or a drop may be seen protruding between the middle and inferior turbinate bodies posteriorly, which when wiped away, in either position, can be made to reappear by changing the position of the head or pressing on the walls of the antrum. The discharge of a straw-colored pus from one side of the nose is always strong evidence of a diseased antrum.

Dr. Cline says (but we believe it is not so certain) that Voltolin's method, as improved by Heryng, is of great value in these cases. It consists of an incandescent lamp placed in the mouth, over which the lips are closed. The patient being placed in a dark room, the bones of the face become beautifully illuminated. A dark shade will outline the situation of the antrum. If the antrum contains pus it will be outlined by a dark spot and a total absence of any illumination—a marked contrast to the opposite or healthy side.

A very simple and efficient method of diagnosis is to inject a few drops of peroxide of hydrogen with a small syringe, armed with a canula, one-eighth of an inch of the distal end being bent at right angles, so as to enter the opening of the antrum. The nose should be well cocainized to avoid pain. If pus be present, it will boil up and fill the nose with a white foam. By using this method, an exploratory puncture will be unnecessary in the majority of cases.

After we have determined that the antrum contains pus, how shall we get rid of it and cure our patient? There are several methods of treatment, but I will only give what I believe to be the best. In recent cases there may be an effort made to restore the antrum by first relieving the swollen and turgescent condition of the turbinates; then follow with injections of peroxide of hydrogen, as before stated, passing the point of the syringe back about half way between the middle and inferior turbinate bodies. This may be followed by light astringents such as—zinc sulphate, 3 to 5 grains to the ounce; silver nitrate, 3 to 10 grains to the ounce; saturated solution of boric acid, or borax; listerine; or a weak solution of the tincture of iodine.

When the case is chronic, there should be an opening made at the most dependent portion of the sinus. Dr. Cline's practice has been to drill up through the alveolus with a drill run by an electro-motor, and then to insert a silver tube, made from coiled wire. Some prefer entering the antrum in the same way, just below the gingivo-labial fold, between the upper portion of the roots of the second bicuspid and first molar tooth, directing the drill upward and backward at an angle of forty-five degrees. In either case the opening should be of sufficient size to admit of free cleansing and washing out of the antrum. A tube of sufficient length to enter the antrum should be neatly fitted, and guarded from entering the antrum by a shield of rubber or wired to the adjoining tooth.

The after-treatment consists of daily or twice daily, washing out the cavity, first with peroxide of hydrogen (commercial strength), followed with a slightly alkaline or carbolized water in quantity sufficient to thoroughly cleanse the cavity. Then, every second or third day, inject a sufficient amount to thoroughly cover the surface, of one of following solutions, as the case may seem to indicate: saturated solution boric acid, 5 to 20 drops of tincture of iodine to 2 drachms distilled water; sulphite of zinc, 3 to 10 grains to the ounce; nitrate of silver, 10 to 20 grains to the ounce; iodoform, 20 grains to an ounce of the oil of sweet almond.

Of these Dr. Cline likes boric acid the best.

Names of Diseases.

There has, in the course of time, crept into medical nomenclature a number of proper names which have been used in connection with certain morbid conditions. The list has grown so long that a reproduction from *Journal de Mèdecine*, January 11, 1891, of the most common, with their symptoms, may prove interesting and not without utility.

Addison's disease—maladie bronzée—disease of the supra-renal capsules.

Albert's disease—fungoid mycosis.

Aran-Duchenne's disease—progressive muscular atrophy.

Argyll-Robertson pupil—one which changes in accommodation, but does not respond to light.

Astley Cooper's hernia—femoral hernia with a multilocular sac.

Barton's fracture—one of the lower end of the radius involving the joint.

Basedow's disease—exophthalmic goitre.

Baudin's law—antagonism of tuberculosis and malaria.

Bazin's disease—buccal psoriasis.

Beclard's disease—hernia through the saphenous opening.

Bell's palsy—paralysis of the seventh nerve.

Boyer's cyst—sub-hyoid cyst.

Bright's disease—albuminuric nephritis.

Brown-Séquard's combination of symptoms—hemiparaplegia with hemianasthesia of the opposite side.

Cazenave's lupus—lupus erythematodes.

Charcot's disease—amyotrophic lateral sclerosis.

Charcot's joint—the enlarged joint of locomotor ataxia.

Cheyne–Stokes breathing—ascending and descending frequency of respiration.

Cloquet's hernia—perineal hernia.

Colles's fracture—one of the lower third of the radius.

Colles's law—that of non-infection of the mother by her syphilitic infant at the breast.

Corrigan's disease—aortic insufficiency.

Corrigan pulse—water-hammer pulse—the pulse of aortic regurgitation.

Corvisart's facies—asystolic facies.

Cruveilhier's disease—simple ulcer of the stomach.

Cruveilhier's paralysis—progressive muscular atrophy.

Donders's glaucoma—simple atrophic glaucoma.

Dressler's disease—paroxysmal hemoglobinuria.

Dubini's disease—electrical chorea.

Duchenne's disease—locomotor ataxia.

Duchenne's paralysis—pseudo-hypertrophic paralysis.

Duhring's disease—dermatitis hepetiformis.

Dupuytren's disease—retraction of the palmar aponeurosis.

Dupuytren's hydrocele—bi-locular (*en bissac*) hydrocele.

E. Wilson's disease—universal exfoliative dermatitis.

Eichstedt's disease—pityriasis versicolor.

Erb's palsy—paralysis of the brachial plexus.

Erb–Charcot's disease—spasmodic tabes dorsalis.

Fouchard's disease—alveolo-dental periostitis.

Friedreich's disease—hereditary ataxia.

Gerier's disease—paralytic vertigo.

Gibbon's hydrocele—that coincident with hernia.

Gibert's pityriasis—pityriasis rosé.

G. de la Tourette's disease—motor incoordination.

Goyrand's hernia—inguino-interstitial hernia.

Graefe's sign—failure of the upper lids to follow the eyes in descent.

Graves's disease—exophthalmic goitre.

Guyon's sign—renal ballottement.

Harley's disease—paroxysmal hemoglobinuria.

Heberden's rheumatism—that of small articulations with nodosities.

Hebra's disease—polymorphous erythema.

Hebra's pityriasis—pityriasis rubra chronica.

Hebra's prurigo—idiopathic prurigo.

Henoch's purpura—purpura with abdominal symptoms.

Hesselbach's hernia—femoral hernia with a multilocular sac.

Hippocrates's facies—that of agony.

Hodgkin's disease—adenitis; pseudo-leucocythemia.

Hodgson's disease—atheroma of the aorta.

Huguier's disease—fibromyomata of the uterus.

Hutchinson's teeth—notched teeth of hereditary syphilis.

Hutchinson's trio of symptoms—notched teeth, interstitial keratitis and otitis of hereditary syphilis.

Jacksonian epilepsy—focal epilepsy.

Jacob's ulcer—cancroid ulcer.

Kaposi's disease—xerodermia pigmentosa.

Kopp's asthma—thymic asthma—spasm of the glottis.

Krönlein's hernia—inguino-properitoneal hernia.

Laennec's cirrhosis—atrophic cirrhosis.

Landry's disease—acute ascending paralysis.

Laugier's hernia—that across Gimbernat's ligament.

Leber's disease—hereditary optic atrophy.

Levert's law—marginal insertion of the umbilical cord with a small placenta.

Littré's hernia—diverticular hernia.

Ludwig's angina—infectious phlegmon of the subhyoid region.

Malassez's disease—cyst of the testicle.

Ménière's disease—labyrinthine vertigo.

Millar's asthma—laryngismus stridulus-spasm of the glottis.

Morrand's foot—one with eight toes.

Morvan's disease—analgesic paralysis of the extremities.

Paget's disease—pre-cancerous eczema of the breast.

Paget's disease—hypertrophied deforming ostitis.

Parkinson's disease—paralysis agitans.

Parrot's disease—syphilitic pseudo-paralysis.

Parry's disease—exophthalmic goitre.

Pavy's disease—intermittent albuminuria.

Petit's hernia—lumbar hernia.

Pott's aneurism—aneurism by anastomosis.

Pott's disease—ostitis of the vertebra.

Pott's fracture—fracture of the tibia.

Raynaud's disease—symmetrical gangrene of the extremities.

Réclus's disease—cystic disease of the breast.

Richter's hernia—parietal enterocele.

Rivolta's disease—actinomycosis.

Romberg's sign—ataxic swaying in the dark or with closed eyes.

Rosenbach's sign—abolition of the abdominal reflex.

Soesnich's ulcer—infectious ulcer of the cornea.

Stellwag's symptom—retraction of the upper eyelid.

Stokes's law—paralysis of muscles subjacent to inflamed serous and mucous membranes.

Storck's blenorrhea—that of the respiratory passages.

Sydenham's chorea—chorea minor—common chorea.

Thomsen's disease—muscular spasm on voluntary movement.

Tornwald's disease—inflammation of the pharyngeal tonsil.

Velpeau's hernia—femoral hernia in front of the vessels.

Volkmann's deformity—congenital tibio-tarsal luxation.

Wardrop's disease—malignant onychia.

Weil's disease—abortive typhoid fever with jaundice.

Werlhoff's disease—purpura hemorrhagia.

Westphal's sign—abolition of the knee jerk.

Willard's lupus—tuberculous lupus.

Winckel's disease—cyanosis of the newborn.

New Operation for Spasmodic Wry Neck.

Dr. W. W. Keen read a paper on this subject before the Philadelphia Neurological Society, Oct. 27, 1890; it is published in the *Annals of Surgery*, Jan., 1891. The steps of the operation are as follows:

1. The field of operation having been shaved and disinfected, make a transverse incision about half an inch below the level of the lobule of the ear, from the middle line of the neck posteriorly, or even slightly overlapping the middle. This incision should be two and one-half to three inches long.

2. Divide the trapezius transversely.

3. Dissect up to the trapezius and find the occipitalis major nerve as it emerges from the complexus and enters the trapezius. In the complexus is an intra-muscular aponeurosis. The nerve emerges from the complexus at a point between this aponeurosis and the middle line, usually about a half inch below the incision, but sometimes higher up, and then enters the trepezius. It is always a large nerve of the size of a stout piece of catgut, and it is easily found if sought for at the right place.

4. Divide the complexus transversely at the level of the nerve. This division should be made by repeated small cuts, so as not to cut the nerve which is our guide, after which dissect the nerve still further down from the anterior surface of the complexus, where it arises from the posterior division of the second cervical. Cut, or better, exsect a portion of the posterior division before the occipitalis major arises from it; so as to catch the filament to the inferior oblique muscle. This divides the *second cervical.*

5. Recognize the inferior oblique muscle by following the sub-occipital nerve towards the spine. The nerve passes immediately below the border of the muscle.

6. Recognize the sub-occipital triangle formed by the two oblique muscles and the rectus capitis posticus major. In this triangle lies the sub-occipital close to the occiput. It should be traced down to the spine itself, and be divided, or, better, exsected. This divides the *first cervical.*

7. An inch lower down than the occipitalis major, and under the complexus, is the external branch of the posterior division of the third cervical to the splenius. When found, it is to be divided or exsected close to the bifurcation of the main trunk. This divides the *third cervical.*

A drainage-tube and horse hairs are to be inserted, and as the patient lies on the back, although the wound is very deep, the condition is most favorable for good drainage. If desired, the posterior muscles can be united by buried sutures, independently of those in the skin. The after-treatment is the same as for ordinary operations.

Terpene Iodide in Diseases of the Lungs.

In the *New York Medical Journal*, February 14, Dr. William H. Gregg says: For the past two or three years I have carried on a series of therapeutical investigations in search of some antiseptic agent that would act as a specific against the development of acute diseases of the lungs, more particularly acute congestion, pneumonia and those catarrhal and throat affections which are so often the premonitory symptoms of more serious mischief. While I have demonstrated to my own satisfaction that these diseases may be cut short, I am not so sanguine that the remedy will prove curative in all cases where a disease is once fully developed, yet further investigation may prove that it possesses specific properties even in these cases.

It has been my desire only to suggest some drug or combination of drugs which will prevent the ravages of the various cocci that are carried into the lungs through the agency of those septic storms which are so frequent in this climate, before an actual disease of the lungs has been established.

The great disadvantage the physician has to contend against in the administration of medicines is the changes they are liable to undergo when taken into the stomach before they finally enter the circulation. It would therefore appear that we ought to administer all of our remedies hypodermically, and perhaps this is the more rational way of obtaining their full benefit. But this mode has its objections. In the first place, it requires more or less skill; besides, it is painful and at times is followed by unpleasant effects.

I believe that terpene iodide enters into the circulation unchanged, from the fact that it acts as quickly as if it were administered hypodermically. It is my judgment that the remedy offers greater success and produces happier results than any other of this class of remedies. While it is a powerful antiseptic, it is comparatively harmless, for, after prescribing it for several years, I have yet to meet with any unpleasant effect. In acute affections of the throat it may be used in spray, while in other cases it may be given to adults in ten-drop doses, on a teaspoonful of sugar, once or twice a day—in the morning and at bedtime. The morning dose should be followed by a glass of milk or bouillon. Larger or more frequent doses are apt to excite too great a discharge of urine.

I have no doubt that terpene iodide will, should it come into general practice, find a wider range of usefulness than that above indicated. As to its value in phthisis pulmonalis, diphtheria and other zymotic diseases, I am at present unable to speak.

Local Treatment of Tuberculosis of the Larynx.

The *Journal de Médecine de Paris*, January 25, 1891, says that Goris uses various astringent powders for insufflation in the treatment of laryngeal tuberculosis, with the object of coagulating the albumin and forming a more or less protective coating, of keeping aseptic the interior of the larynx, and of relieving pain. He uses the following formula of Schnitzler:

℞ Morphinæ acetatis . . . . . gr. iij
Plumbi acetatis . . . . . ʒss
Sacchari lactis . . . . . ʒv
M. Ft. pulvis.

In addition he prescribes:

℞ Iodoformi (vel iodol) . . . . . gr. xv
Sacchari lactis . . . . . ʒijss
M. Ft. pulvis.

or

℞ Iodoformi (vel iodol) . . . . . gr. xv
Cocainæ hydrochloratis . . . . . gr. iij
Sacchari lactis . . . . . ʒijss
M. Ft. pulvis.

or

℞ Acidi tannici . . . . . gr. vijss
Sacchari lactis . . . . . ʒijss
M. Ft. pulvis.

At the same time, he directs inhalations of the vapor of a three per cent. solution of sodium benzoate, adding at each inhalation a half teaspoonful of the following:

℞ Tincturæ eucalypti . . . . . fʒv
Balsami Peruviani . . . . . ʒj
M.

If the laryngeal secretion is excessive, a drachm of terpinol may be added to the preceding.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,

EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

KOCH'S FLUID IN NON-TUBERCULOUS PERSONS.

To determine if injections of the Koch fluid, within the limits prescribed by Koch, produce reaction in healthy individuals, Dr. Erich Peiper (*Allgemeine Medicinische Central Zeitung*, January 31, 1891) injected at the clinic of Mosler, at Greifswald, twenty-two persons in whom evidences of pulmonary tuberculosis were absent. This number included one healthy medical student, one case each, of cystitis that had been relieved, of arthritis, of rheumatic pains at the shoulder, of gastritis already relieved, of sciatica, of gonorrhœa relieved, of a convalescent from typhoid fever, of eczema of the face, of tabes dorsalis, of chlorosis and trigeminal neuralgia, of carcinoma of the stomach, six cases of diffuse bronchitis, one of fetid bronchitis, two of gonorrhœa and one of cystitis. In every instance the fluid was fresh or but a few days old, and was diluted with a five per cent. solution of carbolic acid. The usual precautions were taken. In no case did any complication occur at the site of injection. More than one centigram was only exceptionally used. Four patients failed to react, or showed but slight reaction. Four others had temperatures of 100.7° and a degree of malaise. The remaining fourteen displayed quite decided reactions. Of nineteen who received two milligrams each, four presented a general reaction, with temperatures of from 102° to 104°. Of twenty-one who received five milligrams each, eight displayed evidences of reaction, with temperatures of from 100.5° to 104°. Of sixteen who received one centigram each, twelve reacted, four with temperatures of 100.4°, eight with temperatures of from 101° to 104.5°. The reaction was usually ushered in in from six to ten hours by shivering or a chill. The maximum was soon reached and the temperature slowly fell. On the day following, the temperature, in some cases, was unusually low. In one case, after an injection of one centigram, the fever lasted for two and a half days. The accompanying symptoms were pains in the extremities, headache, flushing, sweating, dyspnœa, irritable cough, increased expectoration and pains in the side of the chest, not so decided, however, as in the reaction of tuberculous patients. Cough was absent in several cases of bronchitis. In two cases, the spleen was enlarged. There was increased frequency of pulse and respiration in proportion to the elevation of temperature. In three cases, in which pus was present, reaction followed upon small doses. A patient with cystitis, in whom there was no reason to believe that tuberculosis existed, reacted promptly to each of ten injections, decided improvement in the local disease taking place.

It is to be regretted that a number of perfectly healthy persons could not be secured for making the investigations. It also remains, of course, an open question

if patients who react to the injections may not have in some part of the body a latent tuberculosis—although to assume this is a pure hypothesis.

It must not be forgotten that the Koch fluid is a potent agent—for good or ill—in the administration of which the greatest discretion should be observed. Extravagant claims should not be made for it, nor should it be condemned merely because injudiciously used. Our own opinion is that it is of no real value as a therapeutic agent, although—as we stated in our first comment on it—we would be glad, for the sake of humanity, if the judgment should prove to be erroneous. It is a curious fact that in the only case, so far as we know, which has been claimed as a "cure" in Philadelphia, the patient died in the Philadelphia Hospital on March 6, a hurried *post-mortem* examination being made by the attending surgeon without securing the presence of the Pathologist of the Hospital.

TREATMENT OF ANEMIA.

It should always be borne in mind that anemia is a symptom. When the removal of the condition which gives rise to it is possible, this should be the first step in the treatment, and it alone may suffice to dissipate the anemia. Sometimes, however, the causative factor eludes detection, or it may be that the disease to which the anemia is due is beyond the reach of treatment. Under these circumstances, the anemia, as such, must be directly attacked. The *Deutsche Medicinische Wochenschrift*, January 29, 1891, contains a brief paper by Dr. Laache, presented to the Section on Internal Medicine, at the Tenth International Medical Congress at Berlin, in which are laid down the lines of treatment of the various forms of anemia.

If worms are present in the intestinal canal, if hemorrhage or other wasting discharge exists, if digestion is impaired, these conditions should receive appropriate attention. For the simple anemias and for chlorosis, in which there is deficiency both of red corpuscles and of hemoglobin, iron is the best remedy. A favorite form in which to administer iron is as Blaud's pill, containing equal parts of dried sulphate of iron and carbonate of potassium. For cases to which this is not suitable, or in which it is not well borne, the lactate or the carbonate of iron, or a solution of the albuminate, may be prescribed, or a soluble salt may be injected subcutaneously. A most important point in the administration of iron is that it must be continued persistently, for long periods, it being remembered that the number of corpuscles is restored to the normal long before the proportion of hemoglobin. Next in importance to iron is arsenic, which has a special application in the treatment of pernicious anemia, in which there is a diminution in the number of red cells and in the total amount of hemoglobin, although the individual red corpuscle contains a relative excess of hemoglobin. To arsenic is also ascribed the property of diminishing the number of white corpuscles, which ought to make it a valuable remedy in the treatment of leukemia.

Of other remedies recommended for the treatment of anemia, many are of doubtful value, while, of a few, some good may be expected in individual instances. Among the latter may be included: transfusion of blood or solutions of common salt, subcutaneous injection of blood, and inhalations of oxygen. Of all the means proposed, the most astounding, perhaps, is blood letting, which, in a few reported cases, is said to have given satisfactory results.

The general management in a case of anemia is not to be neglected. Light and pure air should be provided for. Passive or gentle active exercise in the open air, avoiding fatigue, is to be commended in most cases of ordinary anemia. In pernicious anemia, however, rest in the recumbent posture should be insisted upon; while in intense anemia following hemorrhage,

and in chlorosis, such rest—at least for a time—acts beneficially. In cases in which heat production has not sunk too low, judicious treatment with cold water has a tonic effect. Sea-bathing must be undertaken with extreme caution, and the dietary should not be arranged with a view to the production of fat, but should consist largely of meat, so as to supply the material from which blood corpuscles can be made.

With these general suggestions, it would not be hard for any medical man to arrange a plan of treatment suited to almost any case of anemia, remembering always that the end to be accomplished is to lay up for the patient a stock of vigorous blood which shall support and not drain the tissues through which it circulates.

TREATMENT OF ASTHMA IN CHILDREN.

Dr. Blache, in the *Bulletin Medical*, January 14, 1891, points out the indications in the treatment of asthma occurring in children. At the onset of the attack, inhalations of the smoke from burning leaves of belladonna, hyoscyamus or stramonium, from nitre paper, inhalations of oxygen or of iodide of ethyl, should be tried. These failing, a hypodermic of a little morphine will at once relieve the dyspnœa. Morphine, however, must be used with great circumspection in children. Belladonna, on the other hand, is well borne, and its use may be continued for a long time. A sixth of a grain of the powder or a sixth of a grain of the extract may be given daily. The tincture of lobelia is well borne in large doses. Beginning with twenty drops, the dose may be gradually increased to three drachms in twenty-four hours. Good results have been obtained with the tincture of grindelia robusta, which has also been said to be a specific in whooping-cough. From fifteen to twenty drops may be given at a dose. Inhalations of the vapor of pyridin, as recommended by Sée, mitigate the severity of the paroxysm.

In the curative treatment, the iodides, and especially the iodide of potassium, hold the first place. Their efficacy depends upon an influence upon the brain and medulla, regulating nervous discharges. If the iodides are not well borne or if symptoms of iodism occasion annoyance, tincture of grindelia, arsenic, or inhalations of pyridin or of compressed air, may be substituted.

If the asthma be the result of a diathesis of rheumatism, gout or malaria, or due to disease elsewhere, as in the nose or pharynx, treatment must first be directed to these etiological factors.

To these suggestions may be added a reference to the recommendation of euphorbia pilulifera made by Dr. M. Graham Tull, in the MEDICAL AND SURGICAL REPORTER, March 16, 1889, and May 18, 1889. This drug seems to have a powerful influence upon the course of asthma.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

THE TIME RELATIONS OF MENTAL PHENOMENA. By JOSEPH JASTROW, Professor of Psychology at the University of Wisconsin. pp. 60. Fact and Theory Papers. New York: N. D. C. Hodges, 1890.

The title of this work is sufficiently indicative of the nature of the subject discussed. A careful digest of the literature, with abundant references, is given. The outcome of investigations of this kind is in the direction of facilitating and shortening mental processes and improving methods of education.

The publication will have an interest for physiologists and psychologists.

A MANUAL OF AUSCULTATION AND PERCUSSION. Embracing the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurism. By AUSTIN FLINT, M. D., LL. D., Professor of the Principles and Practice of Medicine and of Clinical Medicine in the Bellevue Hospital Medical College, etc., etc. Fifth Edition. Thoroughly Revised by J. C. WILSON, M. D., Lecturer on Physical Diagnosis in the Jefferson Medical College, etc., etc. 8vo, pp. 268. Philadelphia: Lea Brothers & Co., 1890. Price, $1.75.

Little need be said of a book which has passed through five editions. Of course physical diagnosis can be taught practically only on the living subject. It is impossible to convey adequate ideas of sensation or sound by description, but in conjunction with actual examination a systematic work renders valuable service. Of course, it must never be forgotten that

physical signs are but evidence of physical conditions. Alone they do not establish the diagnosis. In illustration, let us quote as to crackling sounds. They "are not uncommon in healthy persons, at the end of forced inspiration. The fact of their presence at both summits, and the absence of other morbid signs, are the grounds for not considering them as evidence of disease. They are found in health, especially if the binaural stethoscope be employed." Let the student beware of pathognomonic signs and symptoms.

Little is said of functional or hemic murmurs, often described in the course of anemia. We cannot reconcile ourselves to the commonly accepted explanation of these as due to changes in the blood; unfortunately, however, without being able to present a better one. A murmur may be generated by certain peculiarities of the channel through which fluid passes, giving rise to variations in resistance. It does not seem plausible, on the other hand, that variations in the density of the circulating medium should occasion adventitious sounds. We should look for the explanations of these so-called functional murmurs in some transient relation between circulation and respiration.

The little volume commends itself to students and physicians, and its revision by so careful a diagnostician and practitioner as Dr. Wilson enhances the value which is guaranteed by the name of its author.

A PRACTICAL TREATISE ON IMPOTENCE, STERILITY AND ALLIED DISORDERS OF THE MALE SEXUAL ORGANS. By SAMUEL W. GROSS, A. M., M. D., LL. D., Professor of the Principles of Surgery and Clinical Surgery in the Jefferson Medical College, of Philadelphia, etc., etc. Fourth Edition. Revised by F. R. STURGIS, M. D. pp. 173. Philadelphia: Lea Brothers & Co., 1890. Price, $1.50.

This work of the younger Gross is too well known to require extended comment. It has already taken its place among the classics on the subjects of which it treats. While medical literature teems with treatises on diseases of the female generative apparatus, prior to the work of Gross the derangements of the male sexual organs was by English writers a comparatively untrodden field. Even yet, probably, the general practitioner is as uninformed on this subject as though it were some obscure specialty. The work in question has done much to clear the medical atmosphere of a good deal of doubt and uncertainty. The numerous additions and comments of the reviser have been interpolated in the text in brackets. The general practitioner would be well repaid by a careful reading of a treatise which handles in a practical way subjects so common to every-day experience.

CORRESPONDENCE.

Electricity and Pelvic Surgery.

TO THE EDITOR:

Sir: In an article read before the Mississippi Valley Medical Association, 1890, Dr. Sutton says: "These teachings are rapidly becoming ancient history, despite the desperate efforts and exaggerated statements of the advocates of electricity as a curative agent. In regard to the latter, men who did not own a battery, and who had never seen a fibroid tumor removed by an electric current, have written elaborate articles on the subject. Happily for the surgeons, who had about arrived at a consensus of opinion in the surgical methods in the treatment of these cases, these 'lightning bugs' have become in recent months less numerous."

This is sensible talk, with which no logical fault may be found. It is well for the science of gynecological electro-therapeutics that the unfitted and unlettered should drop out. That a man who never owned a battery, and who never saw a fibroid tumor removed, should make blatant claims for something of which he knew nothing, can be equalled only by the equally blatant condemnation of the surgeon who never owned a battery and who never saw a tumor removed. It *is* fortunate for medical advance that such as these should have screamed themselves so hoarse that their voices are no more heard in the land.

In the discussion of this paper, Dr. L. S. McMurtry, of Louisville, said: "Of late, electricity has been much vaunted in the treatment of fibroid tumors of the uterus. Dr. Sutton merely mentioned this agent in his paper, probably purposely, because he knows that electricity does nothing towards arresting or removing these tumors. A peculiar feature about the application of electricity in pelvic surgery is that those who a few years since denied the existence of certain forms of intra-pelvic disease are now foremost in the diagnosis and treatment of these same diseases by electricity. The application of electricity by puncture is fraught with great danger. The speaker has removed a uterine myoma by supra-vaginal hysterectomy, weighing sixteen and a half pounds, in which the entire anterior aspect, which had been accessible to electric treatment, was bound by dense adhesions to the omentum, intestines and abdominal wall, etc., etc."

Now there happens to be some peculiar points in this argument, which are salient characteristics of all similiar arguments made by exclusive laparotomists, which are interesting bits of contemplation. I will first number the *curios*, and then take them up separately for examination.

1. "Dr. Sutton merely mentioned this agent," etc., etc.

2. "A peculiar feature about the application of electricity," etc.

3. "The application of electricity by puncture is fraught with great danger."

4. "The speaker has removed a uterine tumor," etc.

1. Dr. Sutton, if acquainted with the statistics and history of gynecological electrotherapeutics, will not feel flattered at this surmise. The unimpeachable cases on record in which tumors have been arrested by electricity, are numerous and quite as reliable as are any statistics ever brought forward by any surgeon. If Dr. McMurtry does not know this—his argument would be akin to that of a "lightning bug" who never owned a battery—if he does know that such claims are made, but refuses to accept them because they antagonize pet theories of his own, it is not polite to give utterance to such doubts, since men of equally honorable standing with himself have seen and reported such cases. I have seen quite a number "reduced," and so can any one else see these cases if he will. I have never seen a fibroid *disappear entirely*, but other men have, and I believe them. It is "foolish talk" to reiterate all this, because all of it is a *fact*.

2. In no branch of medicine has a greater change taken place then in the pathology of female pelvic disease. What became of all of these modern high-sounding diseases, and of the women who had them, before the modern laparotomist was incubated? Who condemned abdominal surgery, not very long ago, but the surgeons themselves? Did women die of these diseases then, as they are dying since laparotomy has become a fashionable "*fad?*" It *is* nice of the doctor to give the "lightning bugs" credit for recognizing and diagnosticating these troubles, early in their history, and for establishing a conservative system of treatment.

3. This objection is a mere will-o'-the-wisp of the doctor's fashioning. I am speaking, of course, of a puncture in the hands of those competent to make use of it. In the clinic, conducted by Dr. Massey and myself, cases are punctured, high intensities being used, and the patients go to their homes one half hour afterwards. I do not advise this, but with such absolutely poor people, and with no beds at our disposal, we have no alternative. I *have never seen* any bad results following a fibroid puncture, and my experience has been an ample one. But even were it possible to show that such a process is attended with danger, what is the value of such an objection? Is not laparotomy—the alternative—a dangerous operation.

4. Dr. Baldy, than whom no man of equal age stands higher in the surgical literature of this country, told me only a few days ago, that he very rarely if ever had opened the abdomen for the removal of tumors, without finding extensive adhesions, and that a large majority of so-called pus tubes were simply cases of chronic adherent salpingitis. So that all this rumpus about adhesions amounts to nothing. Of course they are adherent—these big tumors—how could it be otherwise, and by what process of ratiocination does one reach the conclusion that adhesions are engendered by electricity?

In the *British Medical Journal*, Feb. 7, 1891, Drs. Williams and Champneys (see *Medical News*, Feb 21, especially the few introductory words of the editor) have an article on "The Operative Treatment of Chronic Disease of the Uterine Appendages" which merits careful reading. In the *Lancet* of January 31, 1891 (quoted in the MEDICAL AND SURGICAL REPORTER, February 21) will be found Sir Spencer Wells' reply to Mr. Lawson Tait. This is also most edifying reading. It might appear to a student of medicine as if the accusation of exaggeration, overstating the case, etc., etc., was really one which applied most directly to the surgeon. Sooner or later there must be reaction in favor of the protection of a woman's pelvic appendages. The time is surely near at hand, for the tread of its march can be heard even now, when it shall be criminal for the surgeon to boast of his recklessness in abdominal work, or to demonstrate before any society a "bucketful" of ovaries and tubes. It is a travesty to call this science, it stultifies intelligence to call it good surgery, and it outrages refinement and common sense to make such exhibitions. It is inexact to claim that operations of this kind cure the patient, when just the reverse is often the case. Many a woman suffers more acutely for years after such an operation than she did before it. I am glad of anything that cries a halt to it, and I am very especially glad that electricity has arisen to show us a better, safer and more conservative plan of treatment, and that the "lightning bugs" have been largely responsible for stemming the tide and turning it in another direction.

Yours truly,

HORATIO R. BIGELOW, M. D.

Philadelphia.

Notes and Comments.

Solution of Shurley and Gibbes for Tuberculosis.

Dr. J. E. Clark, Professor of Chemistry and Physics, Detroit College of Medicine, gives in the *North American Practitioner*, February, 1891, the following account of the manufacture of the solutions recommended by Drs. Shurley and Gibbes.

The main difficulties encountered were the tendency of the gold solution to reduction, and the formation of abscesses following the iodine injection. It was found that both these obstacles were removed by scrupulous cleanliness in all manipulations, and securing absolute purity of the chemicals used. It is an unfortunate fact that the so-called C. P. chemicals, are often so only in name, and that the chemist who wishes to succeed must be an adept in purifying or manufacturing his own. In toxicological analysis where the purity of the reagents is of supreme importance, Dr. Clark has frequently found chloroform, ether, alcohol, etc., bought from good houses, containing impurities, which if undetected might easily have led to erroneous conclusions.

In making the solution of gold and sodium, the first step is the preparation of pure gold. Dr. Clark takes an English gold coin of recent date, which is composed of one part of copper and eleven parts of gold, and thus avoids the trouble of an insoluble chloride of silver which sometimes interferes where the alloy consists of part silver; to the coin in small pieces he adds eight parts of nitro-hydrochloric acid (four parts hydrochloric to one part nitric acid) chemically pure. This solution is then evaporated on the water bath with an excess of hydrochloric acid to nearly dryness, it is then treated with hot water and filtered to separate any chloride which might be present. To this solution is added a solution of pure oxalic or formic acid which will cause the precipitation of any gold which is present, in the form of a brown or greenish-black powder, in from one to forty-eight hours.

This powder is collected and boiled in dilute hydrochloric acid Sp. gr. 1.1, and then washed and dried. To the powder is added eight parts of nitro-hydrochloric acid and the solution evaporated on the water bath to nearly dryness, and allowed to crystallize. Too much heat here or too long evaporation is apt to give an aurous or an acid chloride Au Cl or Au H Cl_2, either of which must be avoided. The result, if the manipulation be properly conducted and the water of crystallization driven off, leaves ruby red prismatic crystals, and not the orange red crystalline needles of commerce.

The next step is the manufacture of the chloride of gold and sodium. The common salt usually contains portions of Ca Cl_2, Mg Cl_2, and Ca S O_4. Dr. Clark either makes the salt from an anhydrous carbonate and hydrochloric acid, or dissolves it in four times its weight of pure water and adds to the filtered solution first Ba Cl_2, and then Mg Co_3, as long as any precipitate falls, filters and evaporates very slowly, skimming off the first crystals that form and rejecting them; those forming last are the pure salt.

Take of the gold chloride 85 parts, and the Na Cl 16 parts and mix each separately in a little pure water, stir together and allow to crystallize at a low temperature, which will give orange colored rhombic prisms. Similar precautions are necessary in the preparation of the iodine solution, as the iodine of commerce all contains more or less impurities, in the shape of graphite, chlorine, oxide of manganese and crude antimony. To prepare it perfectly pure on a small scale, place some in a small deep porcelain scale or earthenware dish, and cover it air-tight with a glass matrass filled with cold water, and apply to the dish a temperature of about 100 C. for two or three hours, allow to cool and the sublimate will be found attached to the under surface of the matrass. It is best, however, to expose the matrass after about 20 minutes' exposure to the heat and look for acicular prisms of a white color and pungent odor, if these are present they should be scraped off with a glass rod and rejected, afterwards the sublimation is to be carried on until it is complete. The fresh iodine is then to be kept in glass stoppered bottles.

To make a non-irritating solution of the iodine for hypodermic use it was found necessary to combine it with water and glycerine. This is accomplished through the medium of potassic iodide. A sufficient quantity, to just produce solution is added to the water and iodine. The glycerine is subsequently added. To purify the potassic iodide which contains a carbonate and iodate it is only necessary to dissolve in ethylic alcohol and filter. The carbonate and iodate are both insoluble in this solvent.

There are details in the way of manipulation which have not been mentioned, but these will occur to any one qualified to undertake their manufacture. Sterilized distilled water is used in all operations.

The question may arise as to why so much care is required in the manufacture of the solutions, and what harm can arise from the presence of minute quantities of organic matter or impurities? It has been found that the smallest quantity of organic matter in the gold solution will produce reduction on its exposure to light, whereas, if made in this manner it can be exposed to the light indefinitely. If a solution of nitrate of silver be made with like precaution it can be exposed in a clear glass bottle to direct rays of sunlight without change, showing that organic material is responsible for the reduction.

The chemical impurities in ordinary mixtures of these substances appear to me to have been the cause of much of the irritation and the abscesses which followed the primary experiments, as, since greater care has been exercised in the manufacture of the solutions, not a single abscess has been reported. During the last month Dr. Clark has supplied a large number of physicians, in the United States and in Canada, with the solotion, without receiving one complaint.

Pain in some cases is said to follow the injection. This can be mitigated by being careful not to inject too deeply, if the muscle is reached pain often follows. Any dilution of the gold solution, unless with sterilized water, will produce a precipitate of the metallic gold.

On Dietetics of Chronic Nephritis.

In a preliminary note in the *Vrâtch*, No. 39, 1890, p. 889, Dr. Nikolai S. Zasïadko, of St. Petersburg, describes a very interesting group of elaborate clinical experiments which he has carried out in order to elucidate the influence of vegetable, animal and mixed dietary on albuminuria, the arterial tension, pulse, dropsy, temperature, body's weight and general nutrition in patients suffering from chronic Bright's disease. In all, ten patients were selected for the purpose. In each case the observation lasted a month, being divided into three equally-long periods, during one of which the patient was kept on a pure vegetable diet; during the second on an animal diet (with addition of bread, from 50 to 200 grams a day), and during the third on a mixed one. The following are the main deductions drawn by Dr. Zasïadko from his researches.

1. Under the influence of a *vegetable* dietary, the daily quantity of albumin in the urine considerably decreases, the arterial tension is lowered, dropsy markedly increases, the pulse becomes slower, weaker and more easily compressible, the patient's general objective and subjective state grows worse (there appear general weakness, listlessness, disinclination to movements, etc.), the appetite gradually disappears.

2. Under the influence of an *animal* diet, the daily quantity of albumin in the urine markedly increases, the arterial tension rises, dropsy decreases, the pulse becomes more frequent and fuller, the bodily weight decreases *pari passu* with the disappearance of œdemas, the daily amount of the urine, its proportion of solid constituents and specific gravity increase, the patient's general state markedly improves (the patient becoming cheerful and stronger, inclined to exercise, etc.).

3. A *mixed* dietary stands midway between a vegetable and an animal one, but comes nearer to the latter, as far as its influence on albuminuria is concerned.

4. The most prominent symptom of chronic nephritis is constituted by a morbid alteration of the blood which is characterized by an increased proportion of water and a decreased one of proteids, hemoglobin and morphological elements. Hence, to restore the normal properties of the blood and to improve the patient's general nutrition, it appears necessary to keep him on a liberal diet abounding in proteids. All apprehensions concerning the development of uremia from such regimen are void of foundation.

5. Contrary to various theoretical objections, brought forward by Lépine and Senator, animal food (butcher's meat, etc.,) does not cause any renal irritation in chronic nephritis and does not give rise to any exacerbation of the chronic renal process. In acute or subacute cases, however, the dietary can be resorted to only with certain caution.

6. An abundant proteid food usually augments the proportion of albumin in the urine, causing the so-called "dietetic albuminuria" (which, however, swiftly disappears on decreasing the proportion of proteids in the patient's food). In view of the fact, the said proportion of albumin alone cannot afford a criterion for appreciating the grav-

ity of the renal process. The patient's dietary must be always also taken in due consideration.

7. In chronic cases, a moderate exercise increases albuminuria but to a slight extent. Hence it can and must be allowed to such patients.

8. According to modern scientific teachings (Gull and Sutton, Dickinson, Meigs, Johnson, Rayer, Küskoff), chronic Bright's disease constitutes a general affection of the vascular system (and not a local lesion of the kidneys alone, as was formerly thought and taught). Hence, the practitioner of nowadays cannot possibly limit his efforts solely to controlling albuminuria, but must strive to improve the patient's general nutrition by means of an appropriate diet. Only such treatment can lead to improvement in the nutrition of the renal tissues.

9. The best dietery for chronic nephritic cases consists in a mixed (animal and vegetable) food. In chronc interstitial nephritis, accompanied by a general weakness, an animal food should predominate in the dietary, while in chronic parencymatous nephritis vegetable food articles with milk should be in a relative excess.

10. Cooked or roasted Italian chestnuts markedly lower the proportion of albumin in the urine, which is, probably, dependent upon their containing tannic acid.

Starvation and Disease.

The importance of nutrition in the treatment as well as in the prophylaxis of disease has been recognized more especially since the time of Graves. It has long been known that hunger and deprivation increase the predisposition to disease.

The *Centralblatt für die Medicinischen Wissenschaften*, January 10, 1891, quotes from *Fortschritte der Medicin*, Nos. 18 and 19, 1890, the conclusions arrived at by Drs. Canalis and Morpurgo as a result of investigations conducted at the bacteriological laboratory at Rome. Pigeons, chickens and white rats, which enjoy a relative immunity to anthrax, were inoculated subcutaneously with anthrax, food being withdrawn before or after the operation.

It was found that pigeons normally enjoying immunity died of anthrax if food was withdrawn simultaneously with making the inoculation. Pigeons which had been starved for six days did not become infected if they were again fed immediately after inoculation; but were infected, as a rule, if they had been starved for a period longer than six days. If food was withdrawn at the time of operation and resumed in two days, the disease was not aborted, though its progress was retarded. Thus it is seen that in pigeons the loss of immunity from anthrax is related rather to interruption in the circulation of nutritive material than to mere wasting of the tissues. If food was withdrawn on the eighth day after inoculation the animals still died of anthrax, a proof that the germs introduced may continue to live for a number of days in the organism and remain virulent. The loss of immunity for anthrax in starving pigeons is not to be explained by the reduction of temperature which takes place, as infection does not follow inoculation if the animals are kept in a bath at a correspondingly low temperature but at the same time are well fed.

To determine whether profound lesions of the digestive apparatus had any influence upon natural immunity, the pancreas, or portions of it, were removed. In these cases, the pigeons were, as a rule, susceptible to anthrax for a short time.

Chickens also became susceptible to anthrax by starvation. Most of the animals died if the inoculation was preceded for from three to seven days by withdrawal of food. In contrast to the pigeons, the chickens retained immunity if the starvation was begun just after inoculation.

White rats remained unsusceptible to anthrax infection in spite of starvation.

[These experiments are of a class which deserve reprobation. The point sought to be established is one which any intelligent man would consider *à priori* highly likely, and which has been abundantly established by clinical experience. The experiments of Canalis and Morpurgo were useless and cruel, and we mention them only to condemn them.—Editor of Reporter.]

Tritopine.

Merck's Bulletin, February, 1891, says: Tritopine ($C_{42}H_{54}N_2O_7$) is a new alkaloid discovered in *opium* last year by Dr. Kauder, chemist in E. Merck's Laboratories at Darmstadt.

Tritopine, a strong base, neutralizing mineral acids, occurs in opium in still smaller quantities than Protopine, recently

described in that journal. It melts without decomposition at 182° C. [359 F.]. It is easily soluble in chloroform, but only with difficulty in ether. It crystallizes from alcohol in beautifully formed transparent prisms—each part of the alkaloid requiring, for solution, about 40 parts of boiling absolute alcohol.

Most of its salts are very easy soluble in water and in alcohol, as for instance the *hydrochlorate*, *sulphate*, *nitrate* and *acetate*. The *bin-oxalate* and *hydro-iodate* are crystalline. The latter is rather poorly soluble in water.

In regard to the toxic properties of tritopine, Dr. Kobert says that, like most of the opium alkaloids (for instance: Thebaine, Papaverine, and others), it exercises a spastic action, *in the manner of strychnine;* so that its application as a narcotic appears to be precluded. When given in lethal dose, its final action is exactly like that of strychnine—that is, *tetanic*.

Army Medical Board.

An announcement was recently made that an Army Medical Board would be in session in New York City during April next for the examination of candidates for appointment in the Medical Corps of the United States Army, to fill existing vacancies. At the time of that announcement there were only five vacancies to be filled. Recent Congressional legislation has, however, permitted the retirement of certain officers, so that there are now fourteen vacancies in the grade of assistant surgeon, with the probability that the number will be increased to seventeen by the time the examining board begins its labors.

As already stated, persons desiring to present themselves for examination by the Board will make application to the Secretary of War, before April 1, 1891, for the necessary invitation, stating the date and place of birth, the place and State of permanent residence, the fact of American citizenship, the name of the medical college from which they graduated, and a record of service in hospital, if any, from the authorities thereof. The application should be accompanied by certificates based on personal knowledge, from at least two physicians of repute, as to professional standing, character and moral habits. The candidate must be between 21 and 28 years of age, and a graduate from a Regular Medical College, as evidence of which, his Diploma must be submitted to the Board.

Further information regarding the examinations may be obtained by addressing C. Sutherland, Surgeon-General U. S. Army, Washington, D. C.

Meeting of the National Association of Railway Surgeons.

At the Kansas City meeting of the National Association of Railway Surgeons last year, it was decided to hold the next meeting at Buffalo May 7, 8 and 9 of this year. But, on account of the meeting of the American Medical Association being set for the same time, it has been decided to change those dates, and to hold the next meeting at Buffalo April 30 and May 1 and 2. To this meeting all Railway Surgeons are cordially invited. Railway Surgeons sending their names and addresses to the Corresponding Secretary will have a copy of the Constitution and Programme sent to them. Those wishing to read papers should send in the titles of their papers without delay. For further information inquiry should be made of A. G. Gumaer, M. D., Corresponding Secretary, Buffalo, N. Y.

Lion Flesh for Food.

The lion is eaten by some African races, but its flesh is held in small esteem. The Zulus find carrion so much to their liking, that, according to the late Bishop Colenso, they apply to food peopled by large colonies of larvæ the expressive word "uborni," signifying in their uncouth jargon "great happiness." David Livingstone, that keen and accurate observer, reminds us that the aboriginal Australians and Hottentots prefer the intestines of animals. "It is curious," he says, "that this is the part which animals always begin with, and it is the first choice of our men." On this point it may be well to remind the civilized reader that the woodcock and the red mullet, or sea woodcock, are both eaten and relished without undergoing all the cleaning processes which most animals used for food among us generally experience to fit them for the table; so that our aversion to the entrails of animals is not absolute, but only one of degree. The hippopotamus is a favorite dish with some Africans when they can get this unwieldy and formidable river monster, and when young its flesh is good and palatable,

but with advancing years it becomes coarse and unpleasant. The Abyssianians, the amiable people to whom, according to the Italian prime minister, his countrymen proposed to teach wisdom and humanity, find the rhinoceros to their taste: so they do the elephant, which is also eaten in Sumatra. Dr. Livingstone describes the elephant's foot as delicious, and his praises will be echoed by many travelers in lands where that sagacious monster still lingers in rapidly decreasing numbers. "We had the foot," wrote the doctor, "cooked for breakfast next morning, and found it delicious. It is a whitish mass, slightly gelatinous, and sweet like marrow. A long march to prevent biliousness is a wise precaution after a meal of elephant's foot. Elephant's tongue and trunk are also good, and, after long simmering, much resemble the hump of a buffalo and the tongue of an ox; but all the other meat is tough, and, from its peculiar flavor, only to be eaten by a hungry man." —*Science*, February 6, 1891.

Nu Sigma Nu Fraternity.

The annual convention of the Nu Sigma Nu fraternity was held at the Wayne Hotel, Detroit, February 13. The society bears the same relation to medicine that the Sigma Phi does to the law, being an under-graduates' secret order, which has chapters in several of the larger cities. The business of the convention in the afternoon, which was presided over by Dr. Waldo E. Clark, retiring grand Æsculapius, consisted of some revisions of the constitution and by-laws, and the election of the following officers for the ensuing year: Grand Æsculapius, R. E. L. Rogers, M. D., Pittsburgh, Pa.; Grand Galen, John L. Irwin, M. D., Detroit; Grand Herophilus, Don M. Campbell, M. D., Detroit; Grand Malpighi, Charles D. Strong, M. D., Brooklyn, N. Y.; Grand Hippocrates, F. W. Robbins, M. D., Detroit.

In the evening the Beta Chapter, of Detroit, gave its first annual banquet, at which the visiting delegates were present as guests.

Salol and the Naphthols.

The *Chemist and Druggist*, February 7, 1891, says: V. Demandre, a pharmacist of Dijon, recently read before his departmental pharmaceutical association, an interesting note suggested by what was at first a mere prescription difficulty. Some time since, he received the following prescription:

℞ Salol . . . . . 0.50 grams
Naphthol alpha . . . . . 0.10 "
For one cachet, send ten such.

On rubbing together the two chemicals in a mortar, a pasty mass resulted, turning to a thick oily liquid. The physician having been notified of the occurrence, the naphthol was left out of the prescription. But the Dijon pharmacist thought the case was worth looking into a little further. Instead of alpha naphthol, he tried beta naphthol with salol in the same proportion as before, and observed that the mixture remained a dry powder. (1) Hence his conclusions that salol is incompatible in powders with alpha naphthol, but quite compatible with the beta variety. (2) That the reaction, a very simple one, will be found useful to distinguish the two naphthols, as dealers are apt to sell one for the other, although their properties are far from being the same.

Mississippi Valley Medical Association.

The Mississippi Valley Medical Association will hold its seventeenth annual session at St. Louis October 14–16, 1891. A large attendance, a valuable programme and a good time are expected. The members of the medical profession are respectfully invited to attend.

For Painful Hemorrhoids.

One is sometimes sorely tried for the means of relieving the pain, tenemus and itching of turgid hemorrhoids. Alvin (*Fortschritte der Krankenpflege*, January, 1891) states that a sponge saturated with water at a temperature of from 127° to 140° F., applied several times daily to the anal region, will mitigate these symptoms.

Notice to Surgeons of the National Guard.

Dr. Senn, of Milwaukee, Surgeon-General of Wisconsin, is desirous of obtaining the name and address of every surgeon of the National Guard in the United States for the purpose of taking the necessary preliminary steps towards the formation of a permanent National Association.

CH. MARCHAND'S

PEROXIDE OF HYDROGEN

(MEDICINAL) H_2O_2 (Absolutely Harmless.)

Is rapidly growing in favor with the medical profession. It is the most powerful antiseptic known, almost tasteless, and odorless. Can be taken internally or applied externally with perfect safety. Its curative properties are positive, and its strength and purity can always be relied upon. This remedy is not a Nostrum.

A REMEDY FOR DIPHTHERIA; CROUP; SORE THROAT,
AND ALL INFLAMMATORY DISEASES OF THE THROAT.

OPINION OF THE PROFESSION.

Dr. E. R. Squibb, of Brooklyn, writes as follows in an article headed "On the Medical Uses of Hydrogen Peroxide (*Gaillard's Medical Journal*, March, 1889, p. 267), read before the Kings County Medical Association, February 5, 1889:

"Throughout the discussion upon diphtheria very little has been said of the use of the Peroxide of Hydrogen, or hydrogen dioxide; yet it is perhaps the most powerful of all disinfectants and antiseptics, acting both chemically and mechanically upon all excretions and secretions, so as to thoroughly change their character and reactions instantly. The few physicians who have used it in such diseases as diphtheria, scarlatina, small-pox, and upon all diseased surfaces, whether of skin or mucous membrane, have uniformly spoken well of it so far as this writer knows, and perhaps the reason why it is not more used is that it is so little known and its nature and action so little understood. . . . Now, if diphtheria be at first a local disease, and be auto-infectious; that is, if it be propagated to the general organism by a contagious virus located about the tonsils, and if this virus be, as it really is, an albuminoid substance, it may and will be destroyed by this agent upon a sufficient and a sufficiently repeated contact. . . . A child's nostrils, pharynx and mouth may be flooded every two or three hours, or oftener, from a proper spray apparatus with a two volume solution without force, and with very little discomfort; and any solution which finds its way into the larynx or stomach is beneficial rather than harmful, and thus the effect of corrosive sublimate is obtained without its risks or dangers. . . ."

Further on Dr. Squibb mentions that CHARLES MARCHAND is one of the oldest and best makers of Peroxide of Hydrogen, and one who supplies it to all parts of the country.

CAUTION.—By specifying in your prescriptions "Ch. Marchand's Peroxide of Hydrogen (Medicinal)," which is sold only in ¼-lb., ½-lb., and 1-lb. bottles, bearing my label and signature, you will never be imposed upon. Never sold in bulk.

PREPARED ONLY BY

A book containing full explanations concerning the therapeutical applications of both CH. MARCHAND'S PEROXIDE OF HYDROGEN (Medicinal) and GLYCOZONE, with opinions of the profession, will be mailed to physicians free of charge on application. ☞ Mention this publication.

Charles Marchand

Chemist and Graduate of the "Ecole Centrale des Arts et Manufactures de Paris" (France).

SOLD BY LEADING DRUGGISTS.

Laboratory, 10 West Fourth Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{50}$ gr.), Atropiæ Sulph. ($\frac{1}{300}$ gr.), Codeia ($\frac{1}{10}$ gr.), Antimony Tart. $\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{50}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

88 Maiden Lane, **New York City.**

BURN BRAE

A PRIVATE HOSPITAL

FOR MENTAL AND NERVOUS DISEASES.

Founded by the late Robert A. Given, M. D., in 1859.

Extensive and beautiful grounds. Perfect privacy. A pleasant, safe and healthful home. Music, games, open-air amusements. The oldest institution of the kind in the United States. Both sexes received.

ARRANGEMENTS MADE FOR CHRONIC CASES.

Located a few miles west of Philadelphia, at Primos Station, on the P. W. & B. Railroad.

Clinical Lecture.

ACUTE SUPPURATION OF THE MIDDLE EAR IN INFANCY.[1]

BY B. ALEX. RANDALL, A. M., M. D.,

PROFESSOR OF OTOLOGY IN THE UNIVERSITY OF PENNSYLVANIA AND THE PHILADELPHIA POLYCLINIC.

Gentlemen: This infant with a mucopurulent discharge from the ear which I now bring before you, suggests many points of importance for our consideration. The coryza, with which its trouble began, is now largely past, but enough of it remains to indicate the truth of the history which is given and to point to the need of nasal treatment. The skin about the ear, as well as on the walls of the meatus, is somewhat excoriated by the discharge; and gives its indication for the most scrupulous cleansing and the use of an emolient and protecting ointment. The tenacious character of the discharge tells us that our best efforts will probably fall short of complete evacuation of the drum cavity from which it comes—for I need hardly remind you that only from the middle ear could this mucus be derived, since there is no mucous membrane in the external canal—and the large admixture of mucus indicates that the alteration of the tympanic lining is not extreme. From this it follows that the collection within the drum-cavity has probably exerted little destructive action upon the drum-head, has forced its way through it only after great distention, and that the perforation is only a separation of the fibers, not a clear, clean hole. A tiny pouting point through which drops of sticky discharge slowly exude is what we are to expect to see when we have cleansed the canal; and even in this expectation we may be disappointed, for the opening may be so inconspicuous that we shall fail to discern it through the narrow swollen canal, into which strong illumination with mirror and speculum seems to penetrate but poorly.

Inspection confirms the anticipation. The perforation is recognizable only by the bead of discharge which protrudes from it and stretches into a long string as I try to wipe it away; and now, hanging from it, serves to locate the invisible opening. Spraying the nares clear with Dobell's solution, and making an application of weak glycerole of tannin with the bent applicator above the soft palate—as much to sweep away any collections there as to obtain any astringent effect—we can inflate the tympanum with the Politzer bag, unimpeded by secretion in the naso-pharynx. As a result we find a new quantity of glairy discharge mixed with air bubbles in the auditory canal, and in removing it can draw away another string protruding from the perforation; after which repeated inflation forces the air through with a fine crackling râle. Light dusting of the bottom of the meatus with boric powder furnishes a slightly astringent and disinfecting dressing; and we will direct the mother to return to-morrow, syringing the ear meantime if any discharge appears. To the excoriated skin we apply an ointment of calomel in vaseline, and could do the same to the nasal mucous membrane; but will employ the gentler procedure of spraying with a protective film of fluid cosmoline, and lightly insufflating the calomel.

At the next visit we may expect to find further decrease of the coryza, a less inflamed auditory canal and perhaps a slight diminution of the discharge. On this last we can hardly yet count. The affection has probably quite a course yet to run; and unless we enlarge the opening in the drum-membrane greatly, so as to gain free access

[1] Delivered at the Philadelphia Polyclinic.

to the inflamed surfaces or adopt other rather heroic methods of treatment, we cannot expect to cut short the attack. With careful watching these simpler measures will doubtless suffice to guide the case to an early and safe termination; so we will hold the more energetic measures in reserve unless more urgent symptoms arise. The nutrition must be looked to, for upon it the satisfactory resolution largely depends; but any medication that might impair digestion is hazardous. In some of these cases inunction with cod-liver oil has distinct value, as combining food, tonic and protection against renewed cold-taking.

Turning a moment from the pathological aspect of this case, I will ask you to study with me some important anatomical points which it brings before us—and this the more especially because the text-books would generally lead you astray. You know that in the new-born infant the annulus or tympanic bone, in the groove of which, as in a frame, the drum-membrane is set, is a separate and distinct bone, forming part of the lower outer surface of the skull. The drum-head, therefore, like the fontanelle, is a portion of the surface of the head, as this specimen shows. But do not imagine, as too many do, that it is to be found immediately within the mouth of the auditory canal. When I pass the cotton-tipped probe down into contact with it, you see that it is about an inch and a quarter in—as deep as in the adult. The external auditory meatus is nearly as long, then, in the infant as in the adult; and, being usually narrower, it is more difficult to illuminate its depths and study the conditions at its bottom. A part of this difficulty is owing to the fact that in the absence of a bony canal there is a much greater tendency of the walls to fall into contact—a tendency which is present only in the outer, cartilaginous portion of the adult canal. To see into the auditory canal, you are instructed to draw the auricle up, back and outward—this serving to straighten out the curves which it naturally assumes in adult life. But you will find this will not do in the infant: the canal is only rendered narrower and more curved by such traction. The drum-head is, at this period, well under the base of the skull, and the meatus extends upwards along the curve of the squama as it passes out. We must draw the auricle *down*, then, in the young child, in order to straighten and dilate the tube through which we are to see; and many fail in their study from not doing so. The auricle must be well drawn down in order to bring the external orifice to the level of the drum-membrane; while in the adult you will find that the axis of the canal almost always tends upwards—that the tympanic end is the higher.

Here we have an explanation of the statement made in almost all of the text-books that the inclination of the drum-head is greater in the infant—that it is more horizontal. Politzer alone, so far as I recall, states the contrary, basing his view on the careful anatomical studies of the point made by Pollak and himself, although Roosa doubtfully accepts this. As you look again at this infant skull with its drum-membranes close together under the base, so that their extreme inclination is conspicuous, it is hard to believe that this does not represent a condition wholly unlike what we daily see in the full-grown state. As seen clinically, the drum-head seems nearly at right angles to the axis of the canal through which we view it, and we must constantly disabuse our minds of this impression. It is hard to believe the demonstration afforded by casts of the auditory canal, by sections of the entire organ or by good anatomical preparations—all agreeing in showing great obliquity of the adult membrane. But it is only by means of a preparation such as this, where the bony lower walls of the canals have been removed on both sides, so that you can see the tympanic membranes just as you do in the infant skull, that their relations to each other can be appreciated and their inclination actually measured. Then it is manifest that, as accurately as we can measure, there is no difference in the inclination. The adult membrane is exactly as near horizontal as the infant's. Great development has taken place in the sphenoid bone, with the general skull growth, pushing the tympana farther apart; the squamous and mastoid portions of the temporals are far larger, and even the petrous portions have apparently grown greatly. How, then, you may well ask, has it been possible that this relation has remained unchanged? Are these two specimens not merely accidentally similar exceptions, not typical examples.

The true relation is what is here shown. I can show you other preparations just like them; while I have never seen any to the contrary. Extraordinary as it may seem, there are some parts of the body which are

of full size at birth. Such are the labyrinth and the ossicles of the ear, and the drum-membrane can probably be included in the same list. A slight growth is perhaps usual in each of these structures; but it is so minute as to be doubtful; and it is even claimed that the ossicles are larger at birth than in later life. The tympanic membrane and the annulus in which it is framed undergo no noteworthy growth in extra-uterine life—marked as is the growth of adjacent structures; so there is no reason to expect that the inclination of the two membranes to each other or to the basal plane of the skull must undergo modification. The assumption of change is gratuitous, and falls at once to the ground when tested anatomically.

If, therefore, your examination of an infant's drum-head is unsatisfactory, the principal anatomical reason is probably to be found in the relative, and perhaps the actual, narrowness of the long canal, which is specially liable to inflammatory swelling. The tympanic membrane may appear small because you cannot see the whole of it—it may seem exceedingly oblique because you are looking at it from above rather than below the horizontal line (yet it must also be remembered that an opaque membrane, especially if much congested so as to be ill-defined, always shows its obliquity markedly)—its posterior portion, if there is secretion within, is apt to be so bulging as to hide the malleus-handle and short process—and any perforation is usually small and recognizable only by the drop of fluid occupying it and giving back a pulsating reflection, or by a protruding bead of more tenacious discharge, as in our present case. Yet the negative side of such a study is so important that it should never be omitted. Polyp formation is quite common in such cases, and is of the gravest importance in causing obstruction of the outflow, with all the consequent dangers to the mastoid and to the brain. Such growths must be promptly removed. The drum-membrane may be somewhat thickened, and the pressure within the tympanum may rise to a dangerous height from retained secretion without doing more than distend yet not rupture it. Paracentesis may then be exceedingly important. Cases may present all the symptoms of meningitis, with convulsions, paralysis and high fever, and yet yield promptly when a protrusion on the upper back wall of the canal, indicating collection in the mastoid antrum, has been discovered and incised. It is far better to foresee such conditions and combat them early, if possible; and a great aid to that end will be furnished by the inspection of which we have been considering the drawbacks and their avoidance. And when our inspection shows none of these conditions of grave omen, we have fair assurance that the case is one which can be safely guided by simple measures to a full and timely recovery.

In such cases, then, as the one before us, cleansing and protection are our needful measures. Cleansing sounds rather simpler and easier than it is in fact. The discharge is often of the tenacious character shown in this case, and both syringing and mopping with cotton are needed to clear the external canal. Even with the inflation of the tympanum, that cavity can be but partially freed of retained secretion; and the blowing in of air from the nose calls for cleansing of its cavities as a pre-requisite to an unobstructed and unpolluted entrance of air through the Eustachian tubes. The infantile tubes are short and wide, the naso-pharynx small; so there is rarely any difficulty in forcing the air into the drum-cavities. The Politzer bag with the olive-shaped tip forms the best inflation apparatus; and the child in crying will furnish all the aid required, such as the adult affords by raising the soft palate in swallowing. After this air-douche, any discharge is to be wiped away from the bottom of the external canal once more—a little mopping with peroxide of hydrogen may do this most thoroughly and perhaps penetrate the perforation, however small; then impalpable boric powder is to be blown in with the aid of a regular insufflator, or of one improvised from a quill. This dusting should be but sparing if the discharge is markedly mucous, for this will but slightly dissolve the powder; and the rule not to use insoluble powders may here include boric acid. Usually the boric powder may be freely used, even to the extent of packing the canal as full as this blowing in will do it; and while some claim that this method does not carry the powder to the bottom of the canal, the slightest observation will demonstrate to you that it does. This gives us an unirritating, aseptic, absorbent dressing, mildly astringent as it dissolves; and while little or none of it may penetrate into the tympanum, it still exerts no little influence on the inflammation. It should be renewed, after cleansing, as often as discharge appears externally. The infla-

tions are to be continued after all discharge has ceased, to further the restoration of the ear to its normal condition and function; and the nasal treatment is also to be maintained in order to forestall, if possible, a new involvement from this source.

COMMUNICATIONS.

PURPURA HEMORRHAGICA AND METRORRHAGIA.[1]

BY M. ANDERSON, M. D.,
PINE BLUFF, WIS.

The case which I report is that of a young woman, 24 years of age, who is a "bleeder" in the fullest sense of the word. She bleeds freely from the nose, the stomach, the bowels, and from the uterus. She is both menorrhagic and metrorrhagic. Her skin is of waxy whiteness and presents ecchymosis on slightest pressure. I was first called to see her six years ago, when she was suffering with extreme, profuse uterine hemorrhage, and what first attracted my attention on entering her room, was the purpuric condition of her skin, the arms and legs being covered with ecchymosis.

From her mother I obtained the following history. The patient was then eighteen years old, and had been subject to nose bleeding from childhood. This frequently followed a fit of anger or some trifling disappointment. She commenced to menstruate at twelve years of age. Menstruation was very profuse, and about a week or ten days before each menstrual period, black spots, from the size of a pea to that of a silver dollar, would appear in her arms and legs, and if she cut, or even pricked her fingers with a needle, there would be considerable bleeding from the wound. Her appetite was variable, and her bowels generally regular, but sometimes the evacuations were black and of the consistency of tar. Her general health was good, except a languid feeling a few days before the appearance of the black spots, and weakness for a short time after loss of blood, and she slept soundly about twelve hours out of the twenty-four. The mother had never suffered any abnormal hemorrhage; nor had any other member of the family suffered so, except an aunt on the father's side, who had profuse menstruation, and had been subject to nose-bleed.

The usual time for the menstrual flow with this girl was six days, but when I first saw her she had been bleeding for five days after the menses should have ceased. I immediately gave her fluid extract of ergot, and also a uterine injection of alum water. I regarded the case as extremely serious, and saw her again in a few hours, in which time she had suffered a slight shock of paralysis.

I requested counsel, but her parents objected, at the same time saying they believed I could do all that any one could. I thanked them for their expression of confidence in me, but told them their daughter was in a very dangerous condition, and they might be better satisfied in the end by having had counsel. I at once set aside the ergot; for, although it had not produced the slightest action on the uterine vessels, I feared its action on the vessels of the brain, as it was evident the paralysis was due to impoverishment of the nerve centres, because, by laying her head lower than her body, so that what little blood she had left could gravitate to the brain, the paralysis was overcome for the time. I then gave her gallic acid, also elixir of iron, quinine and strychnine, and all the milk she could drink. In the meantime Dr. Fox, of Madison, was called, and he pronounced the case almost hopeless, saying I might as well try to hold water in a sieve, as to try to save her. He, however, suggested that I give her a little more iron, which I did, giving her ten drops of the tincture of the chloride in lemonade, but the stomach rejected it. I gave it again two or three times, but with the same result. I then discontinued the iron, feeling that I must guard the stomach; for if the habit of vomiting should become established with her, I should have very little to depend on. I continued the alum-water injections, and was highly gratified at having the hemorrhage cease under their use. I thought I had found the remedy in her case.

The cessation of the uterine hemorrhage was quickly followed by epistaxis. This was controlled by pressure, and for a few days I had hope of her recovery, when from some cause, probably disappointment in not getting what she had her mind set upon, the uterine hemorrhage returned, and persistent vomiting set in. The stomach would not tolerate a particle of anything, not even a drop of water. The retching was almost

[1] Read before the Central Wisconsin Medical Society.

continuous, so that rectal feeding and medication were necessary. I again resorted to my alum-water injection, only to be disappointed in it, although I repeated the operation several times. I then tried plugging the uterine cavity with cotton saturated with tincture of iron, but with no better success. Then I tried subsulphate of iron, and after this, plumbi acetas; but with no better result; for each time the tampons were removed from the vagina, there were also six to eight large coagula to be removed.

The blood in the beginning presented the usual color, and coagulated firmly, but later in the attack it became pale and watery. All this time her sufferings were intense, as all the tissues of the body were starving, and her condition was most distressing. The pupils dilated to their fullest possibility, and paralysis first of one side and then of the other quickly followed. The paralysis was transitory in character, but complete while it lasted. There was numbness of the extremities, panting respiration, and an insufferable sense of suffocation. Her pulse was rapid and weak—at times merely a flutter. Her temperature was sometimes below normal, and her thirst was unquenchable. She wanted something to drink every five minutes; but this only provoked vomiting, and I limited her to half hour time, but this was almost intolerable. I gave her small doses of champagne, which the stomach retained longer than it did anything else; but for three weeks starvation seemed inevitable, and heart failure hourly threatened to close the scene.

Finally, as a last resort, I gave her all the champagne she could drink, hoping thereby to set up a greater state of excitement in the stomach than there was in the uterus, and thus attract the blood from the uterus. In this I acted upon the theory of Dr. I. N. Danforth, of Chicago, "that the blood will rush to the place of greatest excitement;" and in this I was not disappointed, for the hemorrhage ceased, and from this time she began to recover.

She progressed well for three weeks, when epistaxis came again, and she nearly bled to death; but she rallied again, and made a good recovery. I then put her on tonic treatment and on small doses of ergot, continued for a considerable length of time. I recommended careful diet and moderate outdoor exercise, but the nose bleeding came just as often, and so did the black spots, and in less than a year she had another attack, which, in every particular, was as bad as the first. Unfortunately she had lost her desire for champagne; so when stimulants were needed, they had to be given per rectum. This time the subsulphate of iron was the agent which arrested the hemorrhage. After this I stated the case to our highly esteemed Professor of Gynecology, the late Dr. Byford, and he replied that such cases were of rare occurrence and very dangerous, and a cure could not be expected, but said possibly the trouble might be modified somewhat by the continued use of small doses of ergot, and of the mineral acids, especially sulphuric acid. The patient had become disgusted with ergot, so I gave her the acids, but derived very little, if any, benefit therefrom, for in less than six years she has had six of these terrible attacks, each one, if possible, being worse than the preceding. The last attack commenced in May and lasted until the latter part of June of the present year, and was more obstinate than any preceding attack. This, I think, was largely due to excitement, followed by disappointment, but she recovered as usual. The restoration of the lost blood in her case has always been very rapid.

I have tried everything that suggested itself to my mind, as alteratives, tonics and hemostatics; but of all the remedies used locally, Monsel's solution has given better results than any other. Palliative measures are of no use in this case; and it is only by the most persistent employment of both mechanical and chemical means that any good can be derived therefrom. There is no misplacement or morbid condition of the generative organs. The uterus and its appendages, so far as I can determine, are normal, except at the time of profuse hemorrhage; then there is relaxation and lack of tonicity; the cervix is soft and flabby, and the os is sufficiently open to admit the end of the finger. I can attribute this strange condition only to imperfect development of the blood-vessels, the walls of the smaller tubes and capillaries being so thin as to be unable to resist the pressure, and thus readily allow the blood to be continually oozing somewhere. But as these spontaneous hemorrhages show a marked tendency to occur from mucous surfaces, because their vessels are less well supported here than in other parts, it is the more likely to take place from the mucous membrane of the uterus because of the great normal fluctuations in the circulation of that organ.

This is a case which, I think, will tax the patience, the skill and the ingenuity of whoever has charge of it. Gladly would I have given it up years ago, but the patient's parents would not hear of it. However, a few weeks ago, I was somewhat surprised by her father coming in to tell me they had adopted a new plan of treatment with their daughter. I asked if they had concluded to try the hygienic measures I had so long recommended, such as moderate exercise, plenty of fresh air and sunshine, and not allowing her to sleep more than half her time. He replied, "No," but they had taken her to a Roman Catholic priest, who claimed to possess the power to heal, and after fully stating her case to him, he positively assured them he could cure her, and, although he had never seen this young woman before, he told them he had cured twenty just like her. He furthermore said he was the only one in America that had the "specific" for this malady. I remarked that it was very singular that this priest, who is not a physician, should have had so many cures like hers, when not one physician in a hundred in active practice has seen a case just like it.

Dr. Byford, in his excellent work on *Diseases of Women*, in alluding to the hemorrhagic diathesis, mentions one case belonging to this class, that came under his own observation, and the patient died with her second menstrual flow. He said "these cases are of rare occurrence."

I asked the father if he knew what the "specific" was, and he replied, "certain herbs steeped in whiskey, of which a wineglassful is to be taken three times a day." The family are Catholics, and this young women fully believes the priest will cure her; so I shall have an opportunity of seeing, in this case, how far the mind can influence the body.

PERFORATIVE APPENDICITIS.[1]

BY H. REINEKING, M. D.,
SHEBOYGAN, WIS.

It is not my purpose, in presenting this brief paper, to discuss the subject announced in the title, or even to review to any extent its literature, but simply to add to the recorded clinical data bearing on this subject, two cases that recently came under my observation.

Case 1. Henry C., 12 years old, whose previous health had been good, was first seen by me on October 5, 1890. On the evening of October 2, he took a very hearty supper, consisting mainly of baked beans. During the same night he was seized with severe pain in the abdomen, most intense in the epigastric and umbilical regions. There was great restlessness, nausea and vomiting of mucus but not of food. After a dose of castor oil he had what is said to have been a free movement of the bowels the following night. The pain, however, continued with lessened severity, gradually shifting more towards the right side, until it became pretty well localized in the right iliac region, only now and then extending over the entire abdomen.

On October 5, his temperature was normal; his pulse 88, full and strong; his tongue heavily coated; and his appetite completely lost; his bowels had not moved for forty-eight hours. His urine was of normal appearance and readily passed. Vomiting had occurred very infrequently, not more than once in twenty-four hours. The pain came on in very severe paroxysms, commencing in the right side and extending over the abdomen, while tenderness on pressure was limited to the right iliac region. No induration or dulness, however, could be detected.

Large injections of water, glycerine and oil, as well as the repeated internal administration of Epsom salts, were resorted to with a view of removing any irritating material that might be retained in the intestines, but failed to bring on any fecal evacuation. To relieve pain, hot fomentations and small doses of morphia were used. This treatment was continued for several days, while the patient's condition remained unchanged, except that the vomiting ceased entirely, and the paroxysms of pain became less severe and frequent, though but very little morphia was taken. During this time the temperature and pulse varied but little from the normal.

October 13. During the preceding few days dulness and induration had developed in the right iliac region, together with slight tympanites over the remainder of the abdomen. Now indistinct fluctuation could be felt. The temperature and pulse were slightly elevated; the bowels had not moved since the third. There was no vomiting.

October 14. An operation was performed

[1] Read before the Brainard Medical Society, at Milwaukee, Wis., January, 1891.

for his relief. An incision about two and one-half inches long was made, two inches to the left of the right anterior superior spinous process, and a pus cavity was reached without any difficulty. It was intra-peritoneal and contained a large amount of pus, having a strongly fecal odor; but no fecal matter or other foreign body was found. A strong barrier of adhesions protected the general peritoneal cavity. Thorough exploration with the finger failed to detect the vermiform appendix, and it was therefore thought best not to push the search any further. Thorough drainage and antiseptic after-treatment were carried out.

For two days after the operation the wound was in a good condition, the discharge decreased, the pulse and temperature had been nearly normal; still it was evident that the man's general condition had not improved. His appetite was failing; his bowels were just as inactive as before the operation, failing to respond to injections as well as to cathartics, though the latter were not vomited, nor was the pain apparently increased by their use. The man's pain was not severe; and he had no chills or vomiting.

October 17 his temperature was 101° F.; his pulse 100–105; his general condition worse; his tongue dry, red and deeply grooved. Tympanites was becoming well marked. The bowels had not moved for over thirteen days.

Suspecting the existence of some further collection of pus or some constriction that might account for his failing and for the inactivity of the bowels, a second operation was decided on, with a view of finding and relieving such condition if present. The original opening was enlarged both upwards and downwards and the adhesions between the intestines and surrounding parts were carefully severed with the finger. No additional pus cavity was found. The adhesions were quite extensive, but could all be reached and severed by the finger. The cæcum and ascending colon contained considerable masses of hard fecal matter, while the small intestines were filled with fluid feces and gas. No mechanical obstruction was discoverable. The appendix was closely applied to the colon along its under or posterior surface, with no perceptible mesentery, and imbedded in inflammatory exudate, so as to be distinguishable from the colon proper only by the touch. On raising it out of its bed a point was discovered on its lower surface at which fecal matter was oozing out through two small openings.

While this perforation formed an urgent indication for extirpation of the appendix, the anatomical conditions described were such as to make this procedure an extremely tedious and difficult one. Moreover, the patient showed signs of grave shock, and it was evident that he would die under our hands, should we keep him on the table much longer. The oozing points were therefore carefully stitched over with a few Lembert sutures, and the appendix was left. The wound was partially closed and packed and an antiseptic dressing was applied. In spite of all efforts at restoration the patient died in about two hours.

The *post-mortem* examination revealed little that had not been found during the operation. There was no general peritonitis, no mechanical obstruction of the bowels, no leakage, even under pressure, at the point of perforation. The mucous lining of the appendix showed several ulcers, one at the point where the perforation had taken place. Death was no doubt due to the shock of the second operation, added to the already existing exhaustion.

One question that suggests itself in connection with this case is that concerning the cause of the obstinate constipation. In the absence of any evidence of mechanical constriction, it can only be explained either on the theory of a so-called septic paralysis of the bowels, or by attributing it to the extensive inflammatory adhesions and extension of the inflammation to the muscular coats of the intestines. Considering the small amount of morphia taken, and, on the other hand, the persistent efforts made to bring on a movement, all in the absence of vomiting, the total inactivity of the bowels for over two weeks is somewhat remarkable. Another question, and one closely allied to the first, is, whether it would not have been better to have persisted in searching for the appendix at the time of the first operation; as at that time the patient's condition was such that its removal could have been safely accomplished. As the origin of abscesses in this region is almost invariably located in the appendix, it would seem a good rule not to rest until it has been found and examined, unless there are plain contra-indications to such procedure.

Case 2. Frank B., the patient, was 22 years old and a mason. The following is a short synopsis of the history kindly fur-

nished me by the attending physician, Dr. Schaper.

Pain in the right iliac region was first noticed November 7, 1890, and was soon accompanied by vomiting. The bowels were constipated, but acted after taking a laxative. On November 10 the temperature was 100° F., the pulse 76, the tongue coated and dry, and there was a small, firm mass and dulness at the site of the cæcum. Treatment consisted of rest, hot fomentations, repeated small doses of Epsom salts, with sufficient morphine to relieve pain. The general symptoms increased slightly in severity, while the induration and area of dulness enlarged pretty rapidly until November 17, the tenth day after the onset of the symptoms; when the man had a severe chill early in the morning, followed at once by vomiting and a large evacuation from the bowels. At the same time the temperature rose to 105.2° F., the pulse to 120. Both were, however, considerably reduced again in a few hours.

I saw the case with Dr. Schaper on the afternoon of November 17. The swelling in the right iliac region was considerable, extending to the median line, and indistinct fluctuations could be detected.

An incision three and one-half to four inches long, running parallel to the axis of the cæcum and directly over this organ, was made, and this was followed, on opening the peritoneum, by the evacuation of a large amount of pus, having a strongly fecal odor. At the bottom of the abscess I found an oval lump of dry, hard feces, about one-half inch long by one-third inch thick. The appendix was found floating freely in the contents of the abscess, and provided with mesentery only to a limited extent at and near its base. It felt ragged and very much thickened, and tore easily. It was tied with two ligatures close to its attachment to the cæcum, and was removed. Owing to the protective wall of inflammatory adhesions running transversely across tha lower extremity of the cæcum, this part of the bowel could not be drawn out sufficiently to sew the peritoneum over the stump without using undue traction, hence this otherwise important precaution was dispensed with. After complying with all the usual antiseptic precautions, two large drainage-tubes were inserted and the wound closed.

In the further history of the case the following points may be worth mentioning. The temperature and pulse soon came down to the normal and remained so. Fecal odor of the discharge was noted until November 20—three days after the operation. The bowels moved normally, under repeated administration of Epsom salts. The stitches were removed on the seventh, and the drainage-tubes were left out on the tenth day. On the twenty-second day a small subcutaneous abscess was opened near the point where the drainage-tubes had protruded; and three days later two ligatures and a small, hard, shell-like substance were discharged, after which permanent closure took place.

HISTORY OF BACTERIOLOGY.[1]

J. LEFFINGWELL HATCH, B. Sc., M. D.,

LECTURER ON BACTERIOLOGY, AND ASSISTANT DEMONSTRATOR OF MORBID ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA; ASSISTANT PATHOLOGIST TO THE PHILADELPHIA HOSPITAL.

The knowledge of microscopical organisms naturally advances hand in hand with the science of optics, and although the ancients believed the air and water to swarm with beings of such small size as to be invisible to the naked eye, yet it was mere hypothesis and lacked ocular demonstration. To Leeuwenhoeck, a naturalist of Holland, was reserved the honor of discovering and first describing the bacteria. This he did in his work entitled *Arcana Naturæ Detecta*, printed at Delphis Batavorum in 1680. His observations were made with simple bi-convex lenses fixed in a silver mounting. In order to give a comparative estimate of their size, he placed a grain of dust one-quarter of a millimeter in diameter under the same lens with the bacteria, and thus approximately measured them. In spite of instruments so crude, he was able to describe several species, and point out the great rôle that they play in putrefaction and decomposition. He pointed out their presence in water, in vegetable infusions, in the intestines of flies, frogs and chickens, in the feces of man, and recognized the fact of their augmentation in diarrhœa, the first application of them to human pathology. He also demonstrated their presence in the tartar of the teeth and in saliva. It was a great event for those times and made quite

[1] Part of a Lecture delivered before the Philadelphia College of Pharmacy, December 9, 1890.

a stir in the scientific world. One does not know which to admire the more—the nicety of the results announced, or the skill of the experimenter.

After Leeuwenhoeck, the study of microscopical beings was neglected for nearly a century. The difficulty met with in their study, by means of simple lenses, was enough to turn less hardy observers than Leeuwenhoeck to one side, and it was not until the discovery of the compound microscope that anything further was done towards investigating them.

It was Otto Frederic Müller who first applied the compound microscope to the study of the lower organisms, and he described and classified them in his two works. The first, *Vermium Terrestrium et Fluviatilium Historia*, published in 1774, and the second, *Animalcula Infusoria Fluviatilia et Marina*, published in 1786. It was he who had the honor to put in order this crowd of microscopical beings, that the great Linnæus himself believed ought to be placed to one side, and for which he created his genus "chaos," a veritable "caput Mortuum," where all sorts of beings and things are jostled together.

Müller divided the bacteria into two genera: "Monads" and "Vibrios," which names are handed down to us to-day.

The species of the *genus Monas*, incompletely described and badly figured, are scarcely recognizable; two of the ten species that he includes here are certainly short, rod-shaped bacteria—bacilli. He described thirty-one species under the *genus Vibrio*, of which, however, only six are true bacteria. The other forms are really Algæ, Desmids, and Diatoms. His *Vibrio lunula* is a Closterium, his *Vibrio acus* is an Englena, one of the flagellate infusoria. Among the ciliated infusoria to be found in his genus Vibrio are the Paramoecii, the little slipper animalcules, and of the Nematodes, the Anguillulæ.

Lamarck, in 1815–1819; Bruguière, in 1824; and Bary de Saint Vincent, in 1824, have confined themselves in their works to reproducing, intact or but little modified, the gifts of the Danish naturalist, so that up to the year 1833 little progress was made beyond what Müller had done in the eighteenth century.

Ehrenberg is the next to attract attention. Using perfected instruments, he made great progress in the study of microscopical beings. It was at about the time that the botanist Schleiden was carrying on his studies in plant histology, studies the result of which was to agitate the scientific world, and form the basis of what is now known as cellular structure; I refer to his discovery of the cell in 1838. These results, as well as those of Ehrenberg, were due to the rapid advance of optics and the improvement of methods of observation.

In Ehrenberg's grand work, entitled *Die Infusionsthierchen als Vollkommene Organismen*, we find results that are greatly superior to those of his predecessors. He separates those beings which we are considering, from those that had been associated with them, although differing so greatly, and reunites them in his family of the *Vibrionia*, which he describes in the following manner: "Filiform animals without intestines, naked, without external organs, united in chains or filiform series, by the effect of an incomplete spontaneous division." This family comprehends the four following genera:

Bacterium—Little rods, rigid, without vacillating movements.

Vibrio—Filiform bodies, susceptible to undulatory movements like a serpent.

Spirillum—Filiform bodies in an inflexible helix.

Spirochætæ—Bodies in a helix, forming a long flexible string.

Dujardin takes the ideas of Ehrenberg and modifies them a little, in his work entitled *Histoire Naturelle des Zoophytes, Infusoires*, published at Paris in 1841. Here we find new and interesting details concerning the development of bacteria in diverse infusions, and a description of the methods for obtaining and studying the different forms. The four genera of Ehrenberg he condenses into three, fusing the two forms spirochæta and spirillum into one, a movement that has since been approved by many observers, the distinctive characteristics of the two genera having only a relative value of order far too slight as a basis for separation.

The results obtained at this epoch were weighty and for the most part to be preserved; certain ones have been many times confirmed, and are still to be found in the best works.

The achromatic microscope was being perfected day by day, and in the hands of such able experimenters as Dujardin announced conclusions that could be considered as strongly supported, if everything was not made certain.

Up to this time the appearance of these beings so simple, these *animalcules* as they were called, in the infusions, was regarded as a simple fortuitous phenomenon. At the same time very appreciable alterations in the media in question were observed, but they were far from supposing that there was a relation between these two, a relation of cause and effect. If indeed they sought to connect one or the other of them with the phenomenon, it was that they might cause the second to depend upon the first, thus making a law of the ancient adage: "*Corruptio unius, generatio alterius.*" And, as Leeuwenhœck had regarded the considerable augmentation of microscopical beings in the stools of diarrhœa, so many of the *savants*, Linnæus among others, were borne by the simple views of their intellect, to consider these vibrios as the elements of contagion in many pathological states, although nothing positive had been advanced, and not a single fact was forthcoming to support the entirely gratuitous suppositions. The minds of scientists were so little turned from this direction, that Devaine and Rayer, in 1850, pointed out, quite simply and merely as a curious fact, and without attaching any great importance to it, the presence of rod-shaped bacteria in the blood of animals dead from the curious disease called "*sang de rate.*"

The auspicious moment at last arrived, and Pasteur appeared on the scene. He established with certainity the close connection, or the relations of cause, which unite the alterations in certain liquids, certain fermentations, to the development and to the life in the interior of the most simple living beings, the bacteria. In his work on lactic fermentation he has laid the first certain foundation of bacteriology, by the physiological study of these beings. What he demonstrated for this fermentation, he extended to others, and arrived in forming that train of studies which constitutes one of the most glorious scientific achievements of France.

Guided by the principles that as master Pasteur promulgated, Devaine went over the observations that he had made several years previously with Rayer upon the blood of the spleen, and was able to establish by a series of experiments, and a line of able deductions, that the cause of the malady was certainly bacteridian, as bacteria were found in great abundance in the blood of sheep ill or dead from that disease.

Pasteur has shown the way to follow in elucidating in all its details a terrible disease, the ruin of the raisers of the silk worm, "*la flacherie*," as it is called in French, which is manifestly bacteridian in origin. It was the first complete study of a contagious affection, and since then from these remarkable teachings luminous conclusions have been drawn relative to the study of maladies recognized to be of the same origin, when the same question of contagion, of recidivity, of heredity, of media, which play so great a rôle in the etiology, and the pathogenesis of infectious diseases arise.

Koch, following in the footsteps of Pasteur, has made remarkable advances in the science of bacteriology, introducing certain refinements into the technique which have facilitated the study, and laid a basis for a more exact classification.

We must not forget to mention the names of Brefeld, Van Tieghem, Prazmowski and Buchner in connection with Koch, as they have played a prominent rôle in work in which he was the pioneer, and they have all been followed by able investigators in many countries. The great feature of Koch's work was the pointing out of the advantage of a solid medium, but gelatine had already been employed by Vittadini in 1852, and potatoes and turnips had been used in Germany.

Coze and Feltz, in 1872, showed that the profound changes in the blood, in the infectious diseases of human beings, were also due to the bacteria, and they made an exhaustive study of one of the most terrible of those affections, viz.: *septicemia.*

The most beautiful applications of these fecund ideas are found without contradiction in the researches upon anthrax, where men like Koch and Pasteur have exerted themselves to the utmost, and have been able to make the study of this malady the basis of the germ theory of contagious diseases.

Since then this science has advanced with a rapid stride, thanks to the labors of assiduous investigators throughout the world, among whom to be noted as the foremost, besides those already mentioned, are Chauveau, Cornil, Chamberland and Roux, in France; Klebs, Flügge, Gaffky, Löffler, Eisenberg in Germany; Lister, Crookshank and Klein in England; Sternberg, Formad, Shakespeare and a few others in America.

The morphology and the physiology of the bacteria, after having been in great honor, has unfortunately been relegated to a second place, and almost eclipsed by the

interest and splendor of the grand pathological gifts; and in spite of the labors of such botanists as de Bary, Nægeli, Cohn, Zopf, and physiologists like Duclaux and Pfeifer, the progress of bacteriology as a science has been slow.

Much work has been done that is useless, and many erroneous conclusions have been drawn, yet on a whole there has been laid a solid foundation, and ways have been opened along which the careful observer can reap a rich harvest.

Reports of Clinics.

BUFFALO GENERAL HOSPITAL.

GYNECOLOGICAL CLINIC—DR. MANN.

Polypus Uteri.

Dr. Mann presented a woman whose symptoms were so indefinite that no further diagnosis could be made than of some pelvic trouble. Examination showed a polyp projecting from the external os and apparently attached by its pedicle at the internal os. This might be malignant, or an adenoma or a mucous polyp. If it were malignant, Dr. Mann said he would resort to high amputation of the cervix. Referring to the relative merits of high amputation of the cervix and total extirpation of the uterus, he said that he regarded total extirpation as a perfectly justifiable operation. He had done it four times with one death, immediately following operation, due to the growth of the cancer in the broad ligaments. It was so soft that its presence in the broad ligaments could not be diagnosticated at the time of the operation. The three other patients, however, died within a year, from recurrence of the cancer. He had known one patient to live ten years after high amputation, a longer duration of life than had occurred after hysterectomy in his experience. Considering the difficulties and dangers of total extirpation of the uterus, and believing that the duration of life was at least as great after the less radical operation, he preferred high amputation of the cervix—the general opinion of the profession.

After a more careful examination, it was decided that the growth was not malignant, and it was removed with the chain ecraseur, although Dr. Mann does not consider it a scientific instrument, not even believing that it has the advantage of diminishing hemorrhage. The tumor was somewhat modulated, irregularly spherical and about one and a half inches in diameter. After swabbing out the vagina, it was tamponed with pledgets of non-absorbent cotton dipped in hydro-naphthol solution and sprinkled with iodoform.

Dr. Mann advised the removal of such pediculated tumors as soon as their presence was noted. They were almost certain not to be malignant, and they could be easily twisted off with polypus forceps, or snipped off with scissors, and the vagina tamponed. Any one could do this operation. Dr. Mann spoke of his chagrin after being summoned one hundred miles into the country, to operate, to find that the tumor was of this nature.

Although insignificant at the outset, these tumors may later cause much harm. Dr. Andrews, of the Buffalo State Insane Asylum, once called Dr. Mann to operate upon a maniac with the following history. The patient had a little mucous polyp, which the late Dr. Miner wished to remove ten years ago, but operation was refused. The tumor, as is frequently the case, caused profuse menorrhagia, on account of the congestion of the tumor from compression of its pedicle at the menstrual period. These hemorrhages resulted in anemia and neuralgia, the latter affecting the pelvic organs especially. Narcotics and alcoholics were used to control the neuralgia, and the woman acquired both the morphine and the whiskey habit. Her mind had become utterly destroyed. Dr. Mann removed the tumor, the patient made a good recovery from the operation, and within a year she was restored to her family and to society perfectly cured, and she has remained well since.

Dr. Mann advised that after removing a tumor of this sort, the patient be directed to return in a week, so that if other tumors were present they might be removed.

Extra-uterine Pregnancy.

Dr. Mann showed a specimen removed from the pelvis of a woman by abdominal section.

The history was apparently that of an abortion at the third month, but no fetus had been seen. There was a mass to be felt in the pelvis, and from its presence and the history of the expulsion of the decidua with-

out a fetus, the probable diagnosis of extra-uterine pregnancy with rupture was made.

A cyst was found containing several large blood-clots. It proved to be the Fallopian tube, which had burst between the layers of the broad ligament, and the contents of the cyst had dissected their way into the substance of the broad ligament. The cover of the sac was a large piece of omentum, which was removed. The sac held nearly a pint of blood clots. The membranes could be made out indistinctly, but the fetus had disappeared, probably by absorption. After removing the sac, drainage was provided for though the abdominal wound.

PERISCOPE.

Excision of Lupus with Immediate Skin Transplantation.

Dr. Geo. Ryerson Fowler, surgeon to the Methodist Episcopal and to St. Mary's Hospital, Brooklyn, reports in the *British Medical Journal*, February, 1891, a very good result from excision and immediate skin transplantation for lupus. He says: Mrs. O'B., aged 65, was kindly referred to me by Dr. Sidney Allen Fox, of this city, with a well-marked lupus exedens of the nose. The entire integument of the nose, with the exception of a small point at its tip, was involved in the disease, the ulceration extending upon the cheeks, and to the inner canthus of the left eye as well. Beyond the area of ulceration there were several suspicious tubercles. The patient states that the disease began many years ago with what seemed like a small pimple upon the left side of the nose, which, after several years, began to ulcerate. This ulceration progressed slowly, new tubercles making their appearance in the immediate area of the surrounding integument, which in their turn would undergo the ulcerative process. The superficial surface involved at the time of coming under my observation measured 5 ctm. in a vertical direction by 7.5 ctm. transversely.

On April 14, 1890, at St. Mary's Hospital, the following operation was performed under ether: The entire diseased surface was circumscribed by an incision extending through the thickness of the skin to the subcutaneous cellular tissue. This was made to include all suspicious tuberculous tissue. By the use of the scalpel and curette the structures thus marked out were thoroughly removed, stopping short only of periosteum and bony structures. By means of hot salt water compresses and firm pressure the hemorrhage was arrested, but one ligature being required. The patient's left arm in the deltoid region was then disinfected, and Thiersch's method of skin grafting followed, the strips of skin being immediately transferred to the surface upon the nose and face from which the lupus tissue had been removed. The strips were laid side by side, their edges slightly overlapping each other, until the entire surface was well covered in; nine strips were required. The parts were then dressed by being first basket-strapped with narrow strips of oil silk until all the grafts were thus protected. Over this were then laid several thicknesses of gauze wrung out of a sterilized salt solution, the whole being held in place by a moderately firm gauze bandage.

On the third day the dressings were removed and replaced, the oil silk permitting of the lifting away of the gauze compresses without disturbing the transplanted strips. Every strip seemed to have secured a hold, and this was confirmed at subsequent dressings, which were repeated at intervals of two days. The oil silk strapping was found to act most efficiently as a means of maintaining a certain amount of moisture of the transplanted strips, which latter particularly I have found to be quite essential to success in this method of skin transplantation.

As the case progressed, the edges of the transplanted strips, which had been permitted to overlap the healthy skin in order to allow for shrinkage, were gradually trimmed, care being taken to still leave sufficient of the strip to prevent the formation of cicatricial tissue at the point where these joined the limits of the circumscribed area. In fourteen days the healing was complete, but the patient has been kept under observation until the present time for the purpose of determining the curative effects of the skin transplantation upon the lupus. There has not been the slightest suggestion of a recurrence of the disease.

The method of treatment here pursued is that which was introduced to the profession by Senger, of Krefeld. In order to prevent the recurrence of the disease in those cases in which the gap cannot be closed by suturing, and where heretofore it has been necessary to permit of slow granulation and cicatrization of the parts following excision, Senger recommends that skin transplanta-

tion by the method of Thiersch be at once practiced. He describes a case in which he employed this method with success, the disease having made considerable progress upon the cheek and upper lip.

Iodoform-Ether-Glycerin Injections in Septic Cavities.

Dr. John R. Haynes discusses, in the *Southern California Practitioner*, the use of iodoform dissolved in ether and glycerin as an antiseptic in gynecological and surgical practice. There is, of course, nothing new in this application of iodoform, but Dr. Haynes cites cases illustrating a valuable method of treatment. The following was the formula used:

℞ Iodoform . . . . . ℥ss
Ether . . . . . f℥i
Glycerin . . . . . f℥iii

A woman was allowed to retain the decidua of a two-months' miscarriage for ten days, notwithstanding septic symptoms had developed. On the tenth day Dr. Francis Haynes saw the case in consultation. The uterus was held fast by a swollen adherent tube, rendering the subsequent process somewhat difficult. Under chloroform it was dilated with Goodell's dilator, and a large quantity of decidua removed by the curette. Copious irrigation. The temperature fell from 104° to normal, but in two days rose again to 102.6°. After copious irrigation, a portion of iodoform mixture was injected.

The method of cleaning and disinfecting the uterus was as follows: The patient was brought to the edge of the bed, the legs wrapped in blankets, the bed protected by oil-cloth, forming a water shed into a tub. The vulvar hair was clipped, and the vulva was carefully cleaned. The vagina was irrigated with half a gallon of hot water, then with a quart of 1 : 2,000 sublimate solution, then with hot water. A double tube, which had just been boiled, was attached to a fountain syringe and introduced into the uterus under guidance of the finger, taking care not to introduce air. Two quarts of hot water were used; then a pint of 1 : 5,000 sublimate solution, then a quart of hot water. The fountain syringe was now detached and a short piece of rubber tubing attached to the end of the double tube, through which, by means of a large glass syringe, an ounce of solution of peroxide of hydrogen was very slowly injected. Next one ounce of the iodoform mixture was very slowly injected. Of course most of it ran out through the double tube, which was now removed. A pad of thick sublimate gauze was now adjusted to the vulva. Recovery was rapid.

A man had an abscess near the right lobe of the prostate. It was feared that it would break into the bladder or rectum, or both. With a long narrow bistoury, the abscess was reached from the perineum. A drainage-tube was inserted, passing up four and one-half inches, and essentially the same process as that just described was gone through. This was repeated morning and night for three days, when the drainage-tube was removed. Very slight discharge followed, and the man made a rapid recovery.

A woman had peritoneal abscess reaching from the left iliac fossa to within two finger-breadths of the left costal margin, nearly to the lumbar region on the left side, and to beyond the linea semi-lunaris on the right side. It was opened by an incision admitting two fingers; the peritoneum was sewed to the skin, irrigated and drained. Next day the process described was repeated. The temperature, which had ranged from 100° to 104°, went to 99°. On the third day it rose to 99½°, and the treatment was repeated. The treatment in the interval consisted merely in renewing the sublimate gauze, dressing occasionally when it became stained by a thin, yellowish discharge. The patient was kept in bed a month, and at the end of two months she was perfectly well, except that a slight thin discharge continued from the seat of the abscess.

The aim was to repeat the process only when a rise of temperature or the presence of pain indicated that pus was accumulating in the cavity. During the entire treatment the process was repeated three times.

Early Treatment of Otitis.

In the *Medical Record*, February 7, 1891, Dr. Sexton writes: The medical man who sees a case of otitis media which has suddenly developed during the progress of catarrhal inflammation of the air tract of the head, whether consequent on scarlet fever, cold in the head, or other affection, assumes a serious responsibility unless well informed in its management, since under certain conditions a seemingly mild case may speedily

become most painful and grave. I have recently been reminded of the perplexity, not to say apprehension, felt by the conscientious practitioner when untoward symptoms develop, several distressing cases coming under my observation in consultation with other physicians. The urgency of the cases seen was no doubt due to the severe winter weather of late prevailing. I hope I may be permitted to offer some practical suggestions drawn from such experience, since they may be of interest to others when in doubt as to the best course to pursue.

It would be out of place here to go far into the pathogenesis of otitis, but we may assume that acute middle-ear affections are, generally speaking, divisible into two principal groups; namely, mild and severe. The mild ones are usually preceded by more or less earache, which almost wholly disappears on the occurrence of a discharge from the ear. The pain is due to inflammation of the mucous-periosteal lining of the drum (inflammation limited, indeed, for the most part to the atrium of the drum) and the confinement of secretions, which may be either moderate or profuse in quantity. Beyond cleansing the organ by means of cotton-wool pellets and very gentle syringing while discharge lasts, these cases had best be let alone for the most part, inasmuch as they have a tendency to spontaneous recovery. Though those cases often get well despite misguided treatment one should never be lulled into unguarded security, whereby valuable time may be frittered away in useless treatment when severer symptoms may be impending. In a severe case it would seem almost impossible to be mistaken in diagnosis if the ear were properly examined even before the more urgent symptoms fully develop. The pains and headache are soon unremitting, unendurable, more agonizing, perhaps, than the pains of almost any other disease, and they demand instant relief, if attainable.

Much blame, we fear, for children's dreadful sufferings specially, not to mention the imminent danger to life, frequently lies at the door of writers who fail to differentiate between mild and severe cases, and who too often recommend for both of them such treatment as may, for the most part, be found among the rubbish of ancient writings called medical; methods meddlesome and often brutal when zealously employed; liable, indeed, to be followed by sad results, now and in the future. Waste no time, therefore, in temporizing measures, since the relief to be had should be quickly sought. So soon as the pains are great, no relief following the discharge, if any occurs, and the upper edge of the drum-head becomes red and bulging, it may be suspected that the gravity of the symptoms is mostly due to the confinement of secretions in the bony chamber comprising the loft above the main cavity of the drum—the attic of the drum in fact—a space lying almost entirely above that part of the drum which is seen on looking into the ear to be covered by the drum-head. The swelling of the lining membrane of this unyielding bony cavity closes the natural outlet for secretions, which can now only escape from the attic by dissecting their way slowly underneath the membrana flaccida and finally appearing as a tumefaction there or further along the bony portion of the external auditory canal. Finally, the mastoid process or general outer surface of the temporal bone may be invaded with formation of abscess of varying proportions.

The onset of this unfavorable process must be recognized at once if we would prevent extensive trouble; puncturing the drum-head low down, blistering, leeching, poulticing, etc., will do no good; indeed, quite the contrary, since they may distress the patient and increase the local irritation. As the invasion of the trouble is rapid, so the remedy should be sure and swift; no stabbing the drum-head in the dark or fruitless incisions into the canal. Let a careful examination of the parts (patient narcotized if unable to remain quiet—which in children cannot be expected) with the electric lantern worn upon the forehead be made. Fortunately we may now, if timely, relieve the symptoms at the start, by thus liberating the fluids in the attic and establishing drainage, an operation based upon the principle inaugurated in the treatment of these parts by Wilde, who waited, however, until much damage had been done before seeking to give relief by letting out matter presenting at the mastoid process.

Do not, therefore, wait for days while more and more damage is being done, when the extension of inflammation from the seat of the disease may be prevented by a fine incision through the membrana flaccida, a proceeding speedily followed by relief in most cases, and in many by a speedy cure. To make the incision a small, sharp-pointed bistoury, the shank of which is set at a con-

venient angle to its handle, should be employed. The point of the instrument is then to be advanced through the membrana flaccida well up into the attic, and as it is withdrawn a free incision made through any bulging or swollen tissues of the canal in proximity to the membrane.

Any one who has witnessed the immediate relief following the liberation of confined secretions, specially from underneath deep fascia or the periosteum can appreciate the importance of this operation. Of the subsequent treatment but little need be said; it will depend largely upon the injury already inflicted upon the ear; if done early, usually no further special treatment will be required.

Uratosis.

The *Montreal Medical Journal*, January, 1891, says: The term uratosis has been suggested by Sir Wm. Roberts to designate that disordered state of nutrition characterized by the deposition of the crystalline urates in the tissues or fluids of the body. By adopting this nomenclature, several advantages, it is claimed, would follow. First, a distinction would be clearly drawn between the effects of an excess of uric acid in the blood and uric acid precipitated as crystalline urate. What, if any, pathological significance the former condition has was at present unknown. The serious consequence following the latter state were well recognized. Excess of uric acid in the blood was only an exaggeration of a normal state, while deposition of crystalline urates was, in any quantity, a pathological condition. Another advantage claimed is that we would be better able to estimate the relation between the different causes that give rise to uratic deposits. When speaking of "ordinary" gout and "saturnine" gout, we use terms which, in the opinion of Sir Wm. Roberts, would be more truly expressed by "gouty uratosis" and "saturnine uratosis." It being much more likely that the gouty diathesis and lead poisoning, while differing in other respects, had one tendency or vice in common, viz., the tendency to the deposition of the crystalline urates or uratosis.

The separation of the effects of the deposition of the crystalline urates from simple increase of uric acid in the blood was of importance from a therapeutic point of view. In the former, the danger of precipitation, especially in the kidneys, was of a very grave character and called for immediate treatment. By the employment of alkaline remedies, we are enabled to postpone for a long period this deposition, and thereby gain time which should be employed in combating the essential cause.

Etiology of Extra-Uterine Pregnancy.

In the *North American Practitioner*, February 1, 1891, Dr. Bayard Holmes says: The subject of etiology in these sad accidents of reproduction are significant in relation to progress and treatment. The mother is exposed in extra-uterine pregnancy to an immediate and to a remote danger. The immediate danger is fatal anemia when rupture of a tube takes place, and the remote danger is sepsis in a limited hematoma or in a retained dead fetus. In a study of the bacterial condition of dead extra-uterine fetuses which I presented to this Society, my attention was called to the great danger of sepsis. Hematomata in other parts of the body are ordinarily removed by absorption without any febrile disturbance, except that early and transient rise which has been attributed to "ferment intoxication." The case is very different in those pelvic hematomata which are due to extra-uterine fetation. Both the retained dead fetuses and the hematomata in this region become infected, in the great proportion of cases, within six months, and a large percentage of the remainder by the end of the year. This fact, I believe, is to be explained by the cause of extra-uterine fetation, which there is good reason to believe lies in an antecedent infective inflammation in the tubes or the endometrium.

In order that an extra-uterine pregnancy may take place, there must be some *malformation* or *deformity* in the sexual apparatus. It does not take place in the normal condition of the tubes and uterus. That it may be a malformation we can readily see, because the present condition of the human uterus is evolved from a very large and divided uterus which is exhibited in the fetus and the lower animals. We may expect an occasional reversion to the original type and hence a risk of extra-uterine fetation. Such an arrest of development cannot often occur, because anatomists do not find these deformities frequently. Nevertheless pregnancy in a rudimentary form is not unknown. A step further and we have a tubal pregnancy.

Dr. Christian Fenger presented at a recent meeting of the Gynecological Society a tube, in the distal third of which there was a two-months' fetus. Its passage into the uterus seemed to have been impeded by an ovum which had previously attached itself to the wall of the tube and grown so far as to occlude its lumen.

Most cases of extra-uterine pregnancy are preceded by a long term of sterility following an unhealthy puerperium, which in itself points to some deformity in the sexual apparatus, arising from one cause or another. It is probable that most of these cases of deformity are due to a process of inflammation, and that inflammation is due to sepsis, and sepsis is due to infection; that accounts for the presence, in close proximity to this extra-uterine fetus, of septic material which converts the hematoma into an abscess. Of course we must always consider the possibility of pressure atrophy between the heavy, dead fetus and the contents of the bowel (hard feces) opening a communication between the bowel and the fetus and producing infection in that way. That must be considered in these cases, but it cannot well be considered in cases of large accumulations of blood. We cannot consider the possibility of suppuration or any septic decomposition of a large mass of blood without infection; that is impossible. Infection is rare through the circulation, but it is not wholly unknown. Therefore I look upon the indications for operation to be these two: The dangers from hemorrhage and the dangers from sepsis. But the danger from sepsis is imminent on account of the probable etiology of extra-uterine fetation.

The Digestive Troubles of Infants.

The Paris correspondent of the *Archives of Pediatrics*, January, 1891, gives an account of Le Gendre's treatment of the digestive troubles of infants. The causes of these troubles are to be sought in the fact that the babies are bottle-fed. It would appear that French mothers will neither nurse their infants nor employ a wet nurse. When the troubles occur, instead of diminishing the supply of food, which ferments and occasions the disturbance, the infant is given more milk because it cries and is thirsty. Water or a carbonated water would be better. Sometimes the system becomes intoxicated by the products of fermentation, and death ensues.

In the early stages it is proper to suspend alimentation. In the later stages, when there is much fermenting matter in the bowels, empty them with calomel, and then give the antiseptics—resorcin, benzoate of soda, salicylate of soda, salicylate of bismuth, naphthol, etc. If one is called still later, when there is fever, flat belly, no urination, or very little, convulsions and coma, then no purgation or antiseptics are of use; we must then use stimulants to the nervous system, hypodermic injections of ether, camphor or caffeine, mustard baths, or wine baths, while friction is used to the skin. By the mouth, every quarter of an hour, give a teaspoonful of sherry, port or champagne which has been mixed with one-half water. Rectal injections of meat extracts or wine may be tried also, and, indeed, they should be relied upon for some hours afterwards before returning to milk alimentation by the mouth. Even when the milk is used it would be well, in serious cases, to give also, every half hour, before nursing, a rectal injection of one to one and one-half ounces of meat (soup) containing two and one-half drachms of dextrin. If the digestion continues to be difficult, the following potion may be used:

℞ Pepsin . . . . . gr. xv
Acid. hydrochl. . . . . ♏viiss
Sacch. . . . . ℥iiss
Aquæ destill. . . . . f℥iv
M. Sig. Teaspoonful after nursing.

Regulation of Prostitution in Missouri.

The *Weekly Medical Review*, February 21, 1891, says that a bill has been introduced and is now pending before the Missouri Legislature, which provides that the boards of police commissioners in all cities of the State having the same, are required to make a complete list of all houses of ill-fame, and of all fallen women, revising this list as occasion may demand, and furnishing it to the boards of health, giving the names, aliases, ages, and former occupation of the women, together with such particulars as may be of statistical and sanitary interest, the record to be kept in the office of the Clerk of the Board of Health, and to be open to inspection to the members of the boards and the Municipal Assembly only.

Each keeper of a house of ill-fame shall be required to furnish complete information to the board and its agents of the particulars set forth in section 1, to give notice of any change that may take place in ownership or with respect to the inmates. Any person failing to comply with such requirements shall be guilty of a misdemeanor.

The police boards are to set apart a district consisting of not more than one-twentieth nor less than one-fortieth of the total area of the city, and as far as possible outside the residence section, wherein fallen women may live. This district shall be divided into sub-districts, and for each subdistrict shall be appointed a regular physician whose duty it shall be to visit at least once a week each of the houses and women appearing on the list furnished by the board for his sole use and inspection. Such physician shall inquire into the condition of the women, and make such orders as are necessary. He may cause their removal to the hospital or hold them under bond of from $200 to $500. He shall make a weekly report to the Board of Health concerning each house and the condition of the inmates, and the keeper of each house shall pay to him $1 per week for each such inmate, this money to be delivered to the Clerk of the Board of Health, subject to the order of the board. Any person violating the order of such physician, or in any way obstructing him in his duty, shall be deemed guilty of a misdemeanor and fined not less than $20 —provided that any person may within three days of the issue of the order appeal from it in writing to the Board of Health, which shall thereupon grant a final hearing.

The Board of Police Commissioners, upon the request of the Board of Health, shall have the power to suppress any house of ill-fame within any locality they may from time to time designate, or the keeper of which disobeys any lawful order. A fine of not less than $20, nor more than $500, may be inflicted upon any person violating such conditions by persisting in a course contrary to the law.

The boards shall, if necessary for the purpose of carrying out the provisions of the foregoing section, establish a refuge or reformatory wherein fallen women who desire to lead a virtuous life, but are unable to obtain remunerative employment or are physically unfit to perform work, may be sheltered until placed in some position where they can maintain themselves honorably.

Meat Juice and Glycerin Applied Externally.

Dr. E. H. Lewis, of Culpeper, Va., writes to the *Virginia Medical Monthly*, February, 1891, that he had as a patient, a two months' old baby, born in the seventh month of gestation. It was very small—weighing after birth, only about 3½ pounds—clothing and all. In this puny condition, the child took cold and appeared to be threatened with broncho-pneumonia. As a result of its inability to cough up the secretions, spasms set in, and life was almost extinct when I responded to the hasty call. Indeed, for some minutes after my arrival, no signs of life could be detected. Yet by vigorous continuous rubbing the body with equal parts of whiskey and water, life was sustained until evidences of it became apparent.

At this stage Dr. Lewis prescribed a mixture of cod-liver oil and whiskey for friction purposes, hoping thereby to furnish some element of nourishment with the stimulant. But by mistake or misunderstanding in the hurry, a bottle of meat juice and glycerin was substituted, and the contents were rubbed all over the infant's body. In a few hours the child recovered enough to swallow, when the meat juice and glycerin were given in doses of one, two and three drops at a time as the stomach would take it. By this double administration of meat juice and glycerin—rubbing the body with it and dosing it internally—in his opinion the child's life was saved. In thirty-six hours it was taking milk as usual from the bottle, and continued to improve until now it is doing well.

Dr. Lewis says: undoubtedly in this case the skin absorbed enough of the meat juice and glycerin to furnish the requisite nourishment for the time being. And the case demonstrates the fact that the remedy can be administered successfully by the skin.

Numerical Relation of Sexes.

The *Journal of Cutaneous and Venereal Diseases*, February, 1891, cites a paper by Dr. C. Dusing, as stating that the relation of the number of males to the number of females born is a constant one as regards man, animals and plants. In man the numerical relation of male to female is 106 to 100. In horses, male and female, it is 100 to 98.

This relationship in man is subject to va-

riation to a certain extent. For example, during war male births predominate. The absence of a considerable number of men exerts this certain influence. In favorable times not alone are a greater number of children born, but girls preponderate. In unfavorable times fewer female children are born and more boys.

Among the first births in the human species there are relatively many males. This excess is especially seen in the children of those mothers who are advanced in age when they become pregnant, and is attributable to the nutrition of the mother not being up to normal.

From the explanations, it is concluded that the sex is not inherited, but results from a combined action of causes. These factors act not only at the time of impregnation, but at various times after. From the beginning the ovule has a tendency to the development of a certain sex, and the semen possesses the same tendency; both combine at the time of impregnation to constitute one tendency, which determines the sex. Long after impregnation, when the embryo is already developed, the nutrition is still of influence, and can cause a change of tendency even if the sexual organs have begun to develop: as for example the occurrence in the mother of a poor state of nutrition may arrest the development of the female and bring about the development of male organs.

When this late reactionary influence remains absent or is not exerted strongly enough to cause a change in the development of the sexual organs, then the sex is definitely decided.

Boric Acid in Otorrhœa.

In the *Rüsskaia Meditzïna*, No. 30, 1890, p. 470, Dr. M. G. Tzitrin, of Simbïrsk, highly eulogizes the treatment of both acute and chronic otorrhœa by insufflating finely-powdered, pure boric acid. In such cases, where the discharge is profuse, the procedure should be repeated twice or thrice daily; be the secretion but moderate, one application a day is fully sufficient for all purposes. On each occasion, the ear should be previously thoroughly washed out with a tepid 2 or 3 per cent. solution of carbolic or boric acid, and then carefully dried with a plug of sublimate or salicylic cotton-wool, after which as much boric acid should be blown into as is necessary for covering the tympanic walls and the remnants of the drum-head with an equal layer of the substance. No powder should be left in the auditory meatus itself, since the latter tolerates any pulverized substances rather badly. Under the treatment indicated, the purulent flow is said to cease in from 8 to 12 days.

Druggists and Venereal Patients.

The *National Druggist* is published in St. Louis, and it presents in its advertising column, February 1, 1891, the following proposition to its readers.

"To retail druggists. Many of you have heard more or less of the wonderful curative properties of the Cook Remedy Company's Magic Remedy for the Cure of Syphilis.

"If you will mail us names and address of those people whom you know to be affected with syphilis, we will undertake to secure them for treatment. We guarantee to cure, or refund all money. We will reimburse you for postage, and for every patient we get out of those whose names you give us we will pay you $25 cash. Look us up, if you will, and see that we are responsible, and that we will do as we agree. All information will be kept strictly confidential. Some druggists have already been paid by us $125 in a single month.

"Start in at once; it will pay you."

Test for Albumin in Urine.

A test for albumin in urine, proposed by Dr. Adolf Jones, of Vienna, is given in the *Pharmaceutial Record*, December, 1890. It is as follows: Upon a portion of the sample of urine is placed an equal bulk of strong hydrochloric acid without shaking, then from a glass pipette let two or three drops of solution of chlorinated lime fall into the tube. If albumin is present a white ring will be visible at the juncture of the acid and the urine even if present in 1 part to 10,000, which makes this one of the most delicate and easily applied tests.

Menthol for Vomiting in Pregnancy.

It is said that the following prescription is of great value in relieving the vomiting of pregnancy.

℞ Menthol . . . . . 15 grs.
Alcohol . . . . . 5 fl drachms
Distilled water . . . . . q. s. ad f℥v

M. Sig. Dose: A tablespoonful every hour.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,

EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PHYSICIANS' ACCOUNTS.

The *North American Practitioner*, March, 1891, says that there recently occurred in the La Salle County Court of Probate, a case of important interest to all physicians. Dr. S. rendered services, medical and surgical, to a Mr. M. during a period of five years, when Mr. M. died and his will was probated. The doctor's bill (something over $500) was presented, with affidavit, and objected to on the part of the administrators. Upon the hearing, it was shown that the doctor did not keep a ledger, but relied only on his pocket record in which he had made his charges, by signs, such as each individual physician has the habit of using. The doctor swore to each item of entry and attempted to explain what each character used meant. The defense here objected and was sustained by the Court. Then the doctor attempted to prove his books by the old common-law rule, that is: by several witnesses who had settled accounts with him by these books; but they could not tell what charges were indicated by the signs and letters used. Then, by two brother physicians, the doctor tried to show that all physicians used the same kind of books; but they could not tell, from an examination of the books, what the services rendered were.

The judge, in deciding the case, totally excluded the books, and the doctor was defeated. The Court and defendants admitted the equity, that is, that services had been rendered, but the Court was compelled by *the law* to ignore everything because the doctor could not show that somebody else was thoroughly acquainted with his system of book-keeping.

If it be asked: Why did not the doctor keep a ledger and transfer his charges to it? Here again the law steps in and says that only books or memoranda of *original entry* can be used as evidence to prove a claim. So the ledger would not help out.

In discussing the case, the judge suggested two remedies. One that every physician should have a complete index of characters used in the book, and second, that the doctor should tell some disinterested persons, at least two, what his signs meant, so that they could testify to the same when called upon. Even this is of doubtful practicability, and, we think, of more dubious reliability in litigation. The best way to avoid such snarls is to avoid suits for professional services. Where a suit is unavoidable, we believe that it would be better for a physician to produce no books in court, and to rely upon proving his claim without them. If his books were called for by the defense, we think they would have more value as evidence than if the physician brought them forward himself. If—what is not the case—physicians kept books as merchants do, or if they kept them with the design of using them in lawsuits, a different form from that now almost universal in the civilized world would have to be adopted. Each item would

have to be entered in full—words and figures indicating plainly the service rendered and the charge made for it.

But this cannot well be, and physicians may as well know that there never has been published a single pocket record or visiting list which can be used in court as evidence to establish a claim against a debtor, under the rulings of courts which are now in force. This, we believe, is rarely of much consequence, for suits are rare, and in most cases a physician who cannot collect on such evidences of indebtedness as most physicians keep, would do well to remember what Shakespeare makes Dogberry say to the watchman who asked what he should do if a suspicious character would not "stand" when halted in the Prince's name. "Why, then," says Dogberry, "take no note of him, but let him go; and presently call the rest of the watch together, and thank God you are rid of a knave."

ABORTIVE TREATMENT OF SYPHILIS.

The diagnosis of chancre from chancroid is, at times, one of the most delicate, as well as one of the most difficult, in surgery. The presence or absence of induration cannot be relied upon as of infallible significance. It is on account of this uncertainty, that, in the treatment of syphilis, the prevailing method of awaiting the development of secondary manifestations, without the institution of measures directed to the removal of the primary lesion, has found the support it has. Should the venereal ulcer, by its course and sequelæ, prove to have been a chancroid, no harm has been done. If symptoms of syphilis develop, we have the means of successfully combatting them.

In the *Bulletin Medical*, February 1, 1891, Dr. Louis Jullien expresses his confidence in the possibility of aborting or modifying the course of syphilis, by excision of the primary lesion, before adjacent glands have become involved. In his opinion the chancre may be considered analogous to a malignant tumor, the thorough removal of which, with proper antiseptic precautions, is followed by primary union, substituting, in a few days, a process which it would otherwise take weeks to complete. Two cases are reported in which, after excision of the chancre, in one case for a period of more than three years and in another for ten years, there was no subsequent manifestations of syphilis. In a third, reinfection occurred after excision. In other cases operated on, it was thought the symptoms were favorably modified.

In two cases in which glandular involvement had already taken place, injections of calomel were made. These were followed by swelling of adjacent lymphatic glands, for which the designation hydrargadenitis has been created. In neither did secondary symptoms appear.

In one other case of chancre of the glans penis and adjacent prepuce, with pronounced induration, which had persisted for a long period before cicatrization took place, in which corrosive sublimate was administered, no cutaneous eruption had been observed at the 139th day.

In estimating this report, it must not be overlooked that the evidence adduced is presumptive and negative. Every medical man knows that the only infallible sign of syphilis is the appearance of secondary symptoms, and that their absence must always as fully cast doubt upon the accuracy of the diagnosis, as suggest the efficacy of the treatment. Abortive treatment has still some who believe in it, but it is still—in the words of a well-known U. S. Senator—an "iridescent dream."

ELECTRICITY IN THE TREATMENT OF EXTRA-UTERINE PREGNANCY.

The investigations of the last few years have thrown much light upon the subject of extra-uterine pregnancy. Fifteen years ago it was considered a very rare condition, so rare as scarcely to be of practical interest; and when met with, medicine was practically

powerless. The physician stood by with folded hands and saw his patient die of hemorrhage; at the most he gave stimulants and narcotics. Now, it is known that ectopic pregnancy is a common condition, at least, in urban communities. It is well recognized also that its cause is antecedent salpingitis, and, best of all, instead of being almost uniformly fatal, the mother's life can now be saved almost always by prompt abdominal section, and removal of the product of gestation.

The history of the use of electricity in the treatment of ectopic pregnancy is full of interest. Introduced at a time when abdominal surgery was in its infancy, and promising to be a safe and reliable cure for a condition universally regarded as fatal, electricity, in this country, became the recognized method of treatment. This was largely due to the genius of T. G. Thomas. Every candid man must admit that much good has resulted from the labors of those who have advocated the use of electricity in the treatment of this condition. Study of the whole subject was stimulated, and the medical world was prepared for the marvels which have since been accomplished by surgical interference. With the introduction of an ideal method of treatment, electricity is falling into disuse; and would be quite abandoned, but for the efforts of its partisans. But now, even its loudest claimants award electricity only a small field of usefulness. It is universally agreed that after rupture of the gestation sac, with hemorrhage into the peritoneal cavity, electricity is useless. Life can be saved only by prompt operation. This class of cases embraces almost all seen in practice. Where extra-uterine pregnancy is diagnosticated prior to rupture, the advocates of electricity claim that it should be used as a feticide, and that operation should not be done. Under these circumstances, abdominal section yields almost perfect results, and in good hands such cases practically all recover. On the other hand, evidence has accumulated that electricity cannot be depended upon to save life. Cases are on record in which, in spite of its use, the ovum has continued to develop; in which death has occurred from hemorrhage with and without rupture of the sac, while the patient was undergoing, or waiting to undergo, the electrical treatment; and in many cases in which the growth of the ovum has been arrested, a diseased mass has been left in the pelvis, liable to cause peritonitis at any time. These facts are undoubted, and they amply prove that, in this class of cases also (sac unruptured), electricity must be rejected.

The value of treatment of ectopic pregnancy, when extra-peritoneal rupture of the sac has occurred—rupture into the broad ligament—is, at the present time, unsettled. There is reason to believe that this variety of rupture is infrequent. Those who consider it frequent argue that such cases undergo a spontaneous cure, as a rule, and only exceptionally cause trouble when the ovum continues to develop, and the fetus grows until term, or when a second rupture occurs, with hemorrhage into the peritoneal cavity. In this class of cases electricity might be used to destroy the fetus, when it survives the rupture, but the unreliability of the agent will probably prevent its employment, and prompt operation will usually be done.

The evidence is plain that, while electricity was useful before the modern advances in abdominal surgery, its employment at the present time is reprehensible. Its use does not protect the woman from the dangers of rupture and hemorrhage; and, at best, after its use diseased uterine appendages are left in the pelvis.

The experience of the writer embraces nine cases of extra-uterine pregnancy. This experience helps to confirm the modern doctrine that an extra-uterine pregnancy should be regarded as a malignant tumor requiring immediate removal.

It is certain that results have been obtained by operative treatment which fully justify acting on this presumption.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

DISEASES OF THE DIGESTIVE ORGANS IN INFANCY AND CHILDHOOD, with Chapters on the Investigation of Disease, the Diet and General Management of Children, and Massage in Pædiatrics. By Louis Starr, M. D., Late Clinical Professor of Diseases of Children in the Hospital of the University of Pennsylvania, etc. Second Edition—illustrated. 8vo, pp. 396. Philadelphia: P. Blakiston, Son & Co., 1891. Price, $2.50.

The admirable features of Dr. Starr's well-known book are so familiar that an extended review seems unnecessary. The first one hundred pages are devoted to the investigation of disease and the general management of children. These pages are worth the entire price of the book. We wish the second part, on the general management of children, could be read and laid to heart by every mother. The third part treats of massage in pediatrics, and was not contained in the first edition. The author follows Murrell in his descriptions. A point to be remembered, Dr. Starr says, is that those cases in which massage is immediately followed by a sensation of comfort or by refreshing sleep are most benefited by the manipulation. On the contrary, those patients who are stimulated by it, derive little benefit and are perhaps positively injured.

The rest of the book deals with diseases of the digestive organs proper. The author has added, in this edition, sections on alterations in the odor of the breath in disease, on urine alterations, and a detailed account of second dentition and its influence on the health in late childhood: a subject which he thinks has been greatly neglected hitherto.

The whole book is thoroughly clinical, contains a large number of useful formulæ, and is just what every one who has much to do with diseases of children will find helpful every day.

DE LA MALARIA. By Dr. Edouard Pepper, Laureate of the Faculty of Paris. Large 8vo, pp. xvi, 287. Paris: G. Masson, 1891.

Prof. Peter, in his letter prefatory to this volume, writes of the author, "'Living in a village of Algiers, you have not had at your disposition any library,' you say. Well, I congratulate you, for you have described facts in accordance with nature, and free from the influence of foreign ideas." This sentence furnishes a key to the characteristics of the book, although it can hardly be said that one has been uninfluenced by the views of others, who seems to be so familiar with a large variety of practical writers, and with a great variety of remedial measures, although it is true that, living apart from the influence of large cities, large libraries, and educational centres, unusual opportunity seems to have been furnished him to study the natural phenomena of the diseases which he describes, and to report the results of different modes of treatment. Dr. Pepper's book contains detailed reports of the history of a good many cases, and a very full exposition of the reasons for the views he holds in regard to his subject. The author, as an American living abroad, has retained his connection with American literature so as to be able to compare, as he does, the preparations of the American pharmacopœia, for example, with those of the French, sometimes decidedly to the advantage of the former—as in the preparations of phosphorus and hamamelis. His book contains, also, numerous references to American writers and American medical journals, and altogether it is a very interesting study of malaria, especially in its relation to other infectious diseases of cosmic origin. The Reporter does not furnish room in which to give any adequate idea of the exact nature of its contents, but the book may be commended to those who wish to study the views of one who has devoted much time to a subject of great medical importance.

INOCULATION FOR RABIES AND HYDROPHOBIA. A Study of the Literature of the Subject. By Surgeon-General C. A. Gordon, M. D., C. B., Honorary Physician to Her Majesty the Queen, etc. 8vo, pp. xii, 127. London: Bailliare, Tindall & Cox, 1887.

Surgeon-General Gordon belongs to that class of investigators who were not carried away by the rush of professional approval which greeted the announcement of Pasteur that he had a means of preventing hydrophobia. In England, for some time, such an attitude towards Pasteur made men singular, but it is a singularity which has been shared by some of the most prudent and discreet men of Great Britain. Surgeon-General Gordon has written several brochures on the subject of rabies or hydrophobia, and this one is of great interest and value. Opposing senseless scares, it attempts to give a rational notion in regard to the actual manifestations and best treatment of hydrophobia. It is a sensible book and calculated to be useful to all who will consider it with judicial fairness.

Correspondence.

Repeated Puerperal Convulsions.

To the Editor.

Sir: Will you kindly answer through the columns of the Reporter or by letter the following question, which I think important, and on which I am unable to find any literature.

Where puerperal convulsions have occurred in first labors, what are the probabilities of their re-occurrence in subsequent labors?

Yours truly,
W. T. Davison.

Canton, Pa.

[It is well known that about eighty per cent. of eclamptics are primiparæ. Nearly one-third of such primiparæ die. Twenty per cent. of eclamptics are multiparæ. This percentage is made up, not only from those who have recovered from a first attack of puerperal convulsions, but also from the great army of those who have escaped eclampsia in their first labor. One case of eclampsia occurs with about every four hundred labors. Hence, in general, it is evident that if a primipara recovers from eclampsia, the prospect of a recurrence of the disease in subsequent pregnancies is slight.

But while this is true in general, it is not so in particular cases. If the eclampsia be due to chronic Bright's disease, which has antedated the pregnancy, and the first attack does not prove fatal, eclampsia and

death is almost certain to follow, should pregnancy again occur. The same is true if the eclampsia complicating the first pregnancy be due to acute Bright's disease, which becomes chronic after labor.

According to Tyson, when the convulsions are of an apoplectic character, and brain injury results, as hemiplegia, etc., should pregnancy again occur, fatal eclampsia may be confidently expected.

On the other hand, when eclampsia in primiparæ is due to primiposity—irritability of the nervous system, pressure on the kidneys or ureters caused by the tonicity of the abdominal wall—and when neither the brain or kidneys are left crippled by the attack, the probability of a recurrence of convulsions in subsequent pregnancies is not great.—Ed. Reporter.]

A Pin Eight Years in the Body.

To the Editor.

Sir: Eight years ago, Ella W., a Swedish girl, fourteen years old, while dressing, placed a pin in her mouth and accidentally swallowed it. It lodged in the throat, and caused considerable pain and uneasiness for a short space of time—probably an hour—when all pain suddenly ceased, and no more trouble was experienced. About four months ago, while engaged in some culinary work and in rolling up the sleeve of her dress, she noticed a small elevated spot over the internal condyle of the right humerus. Upon examination, the object was soon recognized as the pin swallowed some eight years before.

Being called in to examine the case, I found that the pin was just beneath the skin, and that the pin's head was nearest the surface; and upon making a small incision through the integument, I extracted the pin, which was in a good state of preservation.

At no time during the period of its passage from the throat to its location when extracted has it caused any inconvenience. In fact, it was entirely forgotten.

Having frequently heard of such cases as this, I have never had occasion to meet one until the present occasion.

Yours truly,

H. L. Brush, M. D.

Pleasant Grove, Utah.

Notes and Comments.

Tampon in Menorrhagia.

Dr. W. H. Mays, of San Francisco, has an interesting article in the *Pacific Medical Journal*, March, 1891, in which he advocates tamponing for obstinate menorrhagia.

He refers to the medicinal agents usually employed, the styptics and tonics, the hot douche and the curette, and says that when all these shall fail, as they frequently will, to check the propensity to bleeding, when the physician finds it borne in upon him that the more he treats the case the worse is the trouble becoming, there is a remedy at his command which, fearlessly used, will give him absolute control over the hemorrhage, namely, the tampon.

At the threshold we are likely to be confronted with an old prejudice. Would you dare to arrest the menstrual flow? In one instance where it was proposed to tampon at the end of the first twenty-four hours of mensturation, he was told that the blood would surely "go to the head" and work dire results. The function has been hedged about with a peculiar sanctity, and the dangers of interfering with it greatly exaggerated. Dr. Goodell in a recent paper says: "I have learned to unlearn the teaching that woman must not be subjected to a surgical operation during her flux. Our forefathers taught that the presence of a menstruating woman would pollute solemn religious rites, would turn milk sour, spoil the fermentation of wine, and do much other mischief in a general way. Influenced by hoary tradition, physicians generally postpone all operative treatment until the flow has ceased. But why this delay, if time enters as a factor in the case? I have found menstruation to be the very best time to curette away fungous vegetations of the endometrium, for being swollen they are then larger and more readily removed than at any other time." While we may not agree with this writer as to the advantage of curetting during the flow, the quotation shows the drift of gynecological opinion concerning the supposed danger of interfering with a menstruating woman. So little importance does Professor Loewenthal, of Lausanne, attach to the old superstition, that he advocates the complete and repeated suppression by artificial means of the menstrual flow in chlorosis, and publishes a record of twenty-three cases so treated, all of them with benefit.

In illustration of the use of the tampon in menorrhagia, Dr. Mays related the following case, from his practice.

A. B., aged twenty-seven, had been the subject of menorrhagia for three years before coming to him. The disorder was gradually acquired, its origin being ascribable to no cause that could be gleaned from the patient's history. No particular excess of pain accompanied the molimen, but she simply

bled freely, passing clots after the first day and soaking napkin after napkin throughout a period of four or five days. Most of the period was of necessity passed in bed, owing to prostration. During the inter-menstrual intervals she would drag herself around, weak, pale and nervous, but the exhausting hemorrhages, repeated with unrelenting regularity, were sapping her strength and making her existence a miserable one. She had been under treatment the greater part of this time, and about four months before coming to him had been carefully curetted.

On examination he found nothing abnormal in the position or shape of the pelvic organs. The sound revealed some little elongation of the uterine canal. There was no endometritis.

He explained to her that the mucous membrane being set bleeding, the tendency was to keep on bleeding, and, as in the case of a cut finger, the indication simply was to stanch the hemorrhage by pressure. This he proposed to do each month by the aid of the tampon, after she had lost as much as in his judgment she could afford to lose. She readily consented. So at the next menstrual epoch, after allowing the flow to continue for thirty hours, he proceded to tampon the vagina. Drawing back the perineum with a Sims speculum, pieces of cotton wrung out of an alum solution were packed firmly and tightly, first behind and then in front of the cervix, then at the sides, gradually building a solid mass occupying the whole caliber of the vagina, until the vulva was reached. A compress and T bandage completed the procedure. Four hours later the outermost wad of cotton, which pressed on the urethra, had to be removed to allow of urination. On removing the tampon after forty-eight hours, no evidence of further hemorrhage was observable, and the patient rose stronger than had been customary.

At the next menstrual period, the tamponing was repeated. For some reason the packing was not done so solidly as before, and some blood soaked the tampon and escaped from the vulva, though not much. A month later the tampon, applied on the second day, proved a perfect means of control. So also at the next and at several periods immediately following. The patient has only been "packed" twice during the past six months, as the flow rarely now, with proper care on her part, transcends the natural limit. She was gaining in color and weight, and enjoyed better health than for years previously.

This case is typical enough; it is not necessary, Dr. Mays says, to cite others in support of his argument. The tampon is essentially the thing in what may be called uncomplicated cases of menorrhagia. When subinvolution is acting as the cause, it is often the best remedy to employ. Even where the grosser forms of uterine disease are present it may be recommended, for it should be remembered that menorrhagia alone, by its exhaustive waste, its depraving of tissue, and the nervous and circulatory disturbances it sets up, will, itself, produce uterine inflammations, vegetations, flexions, etc.

Bearing on this subject, Dr. Mays quotes from Dr. Gehrung, whose able article is found in the *Journal of Obstetrics*, November, 1888.

"Every practitioner will recall a number of these pitiful cases of broken-down constitution, nervous to the verge of insanity, complaining of the ills that flesh is heir to, who under treatment improve for a while until the next return of the menses mercilessly destroys all that has been gained. The poor woman passes from the hands of the neurologist to the gynecologist, and then back again, until exhausted in confidence, blood and means. Each in his turn has honestly done his best, each is conscious that each recurring menstruation destroys the fruits of his labor."

"The tampon is the remedy which stands at the disposition of every practitioner, whereby he may regulate the amount of loss in menstruation according to the necessity of the case."

Dr. Bizzell, of Georgia, advocates repression of the menstrual flow in menorrhagia, while other agents prove unavailing or are contra-indicated. Quoting Dr. Taliaferro he says: "By this method we have a marvelous therapeutic resource." Cases that have obstinately resisted other methods yielded promptly to this. He prefers, however, the intra-uterine tampon, which consists of a roll of cotton about the length and thickness of a lead pencil. This is iodoformed and carried up through the os to the fundus with a slender dressing forceps, packing it in tightly. The vagina is also tamponed. It is left *in situ* seven or eight days.

Dr. Mays's experience is against the intra-uterine tampon. On the only occasion on which he tried it, colicky pains of a very violent character ensued, necessitating a speedy

removal of the offending cause. Dr. Gehrung states that in a case in which he resorted to the intra-uterine tampon it made matters worse, the uterus relaxing so completely that blood found its way freely around the plug.

Vaginal tamponing skilfully done will prove entirely satisfactory. Dr. Mays adds that in applying the strips of dampened cotton, it is well to work with two pairs of dressing forceps, one pair to press the tampon in an opposite direction from where the next piece of cotton is to be placed with the other pair.

Treatment of Recent Hernia by Aspiration.

In the *British Medical Journal*, February 7, 1891, Dr. John Hern says: On being called some years since to a case of recently strangulated hernia which I failed, under chloroform, to reduce by taxis, finding the tension in and distention of the protruded gut apparently the main obstacle to reduction, I emptied it by means of my hypodermic syringe, with the result that reduction was at once easily accomplished. I have since repeated the operation on thirty-two occasions, in twenty-eight of which reduction was readily accomplished, and in the remaining four, three were, subsequent to aspiration, subjected to the usual operation (with one death from gangrenous gut), and one steadfastly preferred death to further operation, and succumbed on the tenth day. In neither of the three cases of herniotomy could any traces be found of the previous aspiration, due I think, to two causes, the small size of the needle used and the arrangement of the muscular fibers in the wall of the gut.

The class of cases which have appeared to me most suitable for the operation are recent cases—36 to 48 hours or less; where the patient or friends refuse to submit to herniotomy. The simple aspiration can be designated "doing a little something." The advantages claimed for this procedure are:

1. It avoids the delay almost inseparable from the herniotomy, for example, gaining consent of friends, procuring adequate assistance, etc.

2. It avoids rough and heroic attempts at reduction by taxis by placing in the hands of the general practitioner a means of reduction easy of application, and requiring no extensive surgical skill for its performance, and, moreover, a proceeding, which, by reducing the tension of the protrusion, lessens the danger of the taxis subsequently employed.

3. It avoids the risks of pyemia and septicemia, inseparable from all operations in which skin is divided.

Let us consider in how far this operation is based on a consideration of the anatomical and pathological conditions present. We must remember that the internal abdominal ring, the inguinal canal, the external abdominal ring, the crural ring, the crural canal and the saphenous opening in the fascia lata of the thigh are all bounded chiefly, if not solely, by aponeurotic structures, which have become thickened and resistant although the openings have all become dilated. The margins of these openings forced back and thickened offer a strong passive resistance, so that if the protrusion becomes distended in any way by feces or flatus, the neck or narrow portion is so wedged into these fascial openings or canals that it becomes compressed, the venous circulation impeded (both arteries and veins are, of course, compressed, but the thicker coats of, and the greater force of circulation in, the former render them less affected by the pressure), the proportion between the protrusion and the opening or canal through which it has descended becomes so altered, that the hernia becomes irreducible. Now, seeing that (in recent cases, at any rate) it must be the distention of the protrusion which is the main obstacle to reduction, there having elapsed no time for the effusion of lymph or other inflammatory changes to occur, having failed to reduce by taxis, it appears to me to be a perfectly justifiable proceeding to at once empty the protrusion of whatever fluid or flatus it may contain, and having thus lessened its bulk, to reduce by taxis.

Impure Milk in Large Cities.

The *New Orleans Medical and Surgical Journal*, February, 1891, says editorially: Persons residing in the country, or in small towns away from the great centres of trade and competition, have no idea of the many frauds perpetuated by the vendors of the commonest articles of food consumed in large cities. Not least among these is the adulteration of milk with dirty water, or some other substance designed to give it a creamy appearance and cause it to pass

muster before the dreaded lactometer of the officers of the Board of Health.

It has now become the practice in all cities to keep dairymen under surveillance, so that at least the proportion of adulterants added shall be comparatively small. New York and Chicago and other cities have regular milk inspectors, whose sole duty is to procure and analyze samples of this article offered for sale, and to prosecute criminally all persons who sell other than the natural secretion of the cow. Our own Board of Health has for the past five years made regular examinations of milk, and, by following up the offenders to the recorder's court, has succeded in materially improving the standard of milk sold in the city of New Orleans. Some points of general interest were brought forward in a recent report of the chief sanitary inspector, and we will venture to quote a portion of it, as the conclusions to be drawn therefrom are obvious. We can see from this what an easy thing it is for the public to be imposed upon and cheated by their milkmen, to whom they are paying the highest prices for the poorest quality of milk.

This is bad enough, but when we consider who are the persons consuming this fluid and what is the character of the adulterant consumed, the question comes home to us more directly as medical men. We have simply to refer to our mortuary records for May and June of any year and study over the large mortality among children from the bowel diseases, and then, when we think of the sour, stale, watered or adulterated milk that many children are fed upon, we may, perhaps, be willing to discard the antiquated idea of "teething" being a cause of most of these complaints, and attribute a larger proportion of the deaths to improper nourishment.

The substances usually used for adulterating milk are starch, sodium, chloride, borax, chalk, glycerine and bicarbonate of soda. When milk has been skimmed and watered its creamy appearance may be restored by the addition of condensed milk from cans, a common practice in New Orleans.

But what seems to us to be most injurious of all the substances added to milk by the New Orleans dairyman is simple water. This water is from cisterns or wells situated in the swamps back of town and is often teeming with the germs of malaria. Besides, there is the danger to milk from cows drinking ditch water, from which a number of apthous diseases are known to have arisen. Much more might be said upon the danger of impure milk to young children, particularly in reference to tyrotoxicon, a poison generated in stale and sour milk, but we shall have more to say on this subject at another time.

In conclusion, we heartily endorse the following assertions of Mr. J. Lewis Smith:

"In order to obtain milk of the best quality, it is necessary to procure it from a dairy remote from the city, where there is good pasturage, an abundant supply of water, and the health of the cows is promoted by out-door life in open meadows. Stabled cows, in or near the city, fed with distillery food, hay, and in part by kitchen refuse, do not furnish good milk. Such cows are likely to have dirty udders, and their milk, chemically inferior to that of pastured cows, becomes in the open pails the receptacle of bacteria, which are abundant in stables of ordinary cleanliness. Milk, therefore, that is suitable for the nursery in the summer months is obtained at a distance from the city, where cows have the range of the fields, and lie at night in the open air upon the grass."

The Vital Statistics of New York State in 1890.

The *New York Medical Journal*, February 7, 1891, says: The annual mortality-sheet of the New York State Board of Health has appeared for the year 1890, giving the total deaths by eight sanitary districts, by months, and by the usual principal causes. The deaths for the whole State, with a small correction for the non-reported mortality in some rural sections, were 127,630, in a population estimated at 6,000,000; this is equivalent to a death-rate of 19.6 to the 1,000. The mortality from zymotic diseases was less than in recent years, a decline being registered in scarlet fever, diphtheria, typhoid fever, and diarrhœal disorders. Measles showed a marked elevation. Smallpox caused four deaths. Epidemic influenza is estimated to have caused not fewer than 5,000 deaths in the early months of the year, but it did not operate to raise the zymotic mortality, for the reason that a large proportion of its deaths was certified under the head of respiratory and other local causes. There were 18,000 deaths from respiratory diseases, a number greatly in excess of

former years; this is non-inclusive of consumption, which was charged with 13,800 deaths. From unclassified causes there were 18,728 deaths.

Diagnosis of Previous Pregnancy.

From a medico-legal point of view it is sometimes of the greatest importance to determine whether a woman has ever borne a child or not. According to Dittrich, as quoted in the *Deutsche medizinische Wochenschrift*, January 29, 1891, from the *Prager medizinische Wochenschrift*, microscopical examination reveals hyaline degeneration and necrosis of the muscular tissue of the uterus and, in rare instances, of the muscular fibers of the tunica media of the arteries as well, in cases in which a woman has been pregnant even though the gestation has been prematurely terminated.

Medical Attendance for the Poor in Richmond.

The *Virginia Medical Monthly*, February, 1891, says that Richmond, with its nearly 100,000 population, has no city hospital, except the hospital wards in its almshouse. No other city, in Europe or North America, of anything like its population, so far as we know, is without its distinctive city hospital for the cure of its sick or wounded working classes. The City Council has just voted $2,000 annually, to be divided among four physicians, to be elected, located in different parts of the city, whose duty it shall be to attend the deserving poor of their respective four districts of the city, without charge.

The Medical Law of Alabama.

The *Alabama Medical and Surgical Age*, February, 1891, says that the "Penalty Bill," which recently passed the Legislature, gives Alabama a model medical law, and places the State Medical Association on a safe and sound basis. The penalty bill, as it passed the Legislature, provides that any person practicing medicine or surgery in this State, without having first obtained a certificate of qualification from one of the authorized Boards of Medical Examiners of this State, shall be guilty of a misdemeanor, and on conviction thereof shall be fined not less than twenty-five dollars nor more than one hundred dollars. Provided, that this act shall not apply to any doctor practicing medicine in Alabama who is a graduate of a reputable medical college, and who has complied with the law by having his diploma recorded by the Judge of Probate in the county in which he is practicing.

The *Age* says: "Much credit is due to the committee appointed by the Montgomery County Medical Society, consisting of Drs. Baldwin, Gaston, Blue, Wilkerson, Hill, Sealy and Andrews, for the work they did during the session of the Legislature. The irregulars had one or two men on the floor, and used the newspapers for all they were worth, and occasionally resorted to circulars, but this committee, faithful to themselves, their society, the medical profession and the people of Alabama, was able at every point to combat the inroads of the demagogue, upset the schemes and plans of the irregulars and prevent the evils which would have resulted from such vicious legislation as they desired. We cordially welcome all worthy physicians to Alabama, and in doing so, we assure them of fair, just and honest treatment, regardless of name, school or previous condition, but the Legislature of Alabama has said that the Medical Examining Board must protect the people from the imposition of quacks, demagogues and incompetent men, and by the authority invested and for the sake of suffering humanity, and for the protection of the people, we promise that our Boards of Examiners will be equal to the task."

Association of American Physicians of Berlin.

About forty American and Canadian physicians held a meeting on February 19, 1891, at Berlin, in order to found a permanent organization such as exists in Paris, London, Edinburg and Vienna. Prof. Miller, of the University of Pennsylvania, now Professor at the University of Berlin, called special attention to the fact that such an organization would not only greatly benefit the physicians who remain here for purposes of study, but also that it would call the attention of Germany to the forward tendency of American medical science. He strongly urged the publication of the transactions of the Association every year. Permanent organization was effected, Dr. Judson Daland, of Philadelphia,

being elected President, and Dr. F. Weber, of Milwaukee, Secretary,

Prof. Miller, Dr. Amos, of Iowa, Dr. H. Douglas, of New York, and the President and Secretary were elected as a Committee on Constitution.

Dr. H. T. Brooks, of New York City, Dr. Louis Frank, of Louisville, Dr. Crystal, of Baltimore, Dr. Neal Mitchell, of Florida, Dr. Marple, of New York, and Dr. Kennedy, of Montreal, were appointed a Committee on information to new-comers, and organization of special private courses.

The objects and scope of the society are:

First, The arrangement of medical work and the formation of special private courses so that any desired instruction may henceforth be obtainable at this University.

Second, The giving of advice to new-comers regarding instruction, lodgings, books, instruments, etc.

Third, The reading and discussion of papers of general interest and the exhibition of patients and demonstration of specimens in all lines of work taken up by members.

Fourth, The furthering of mutual ends by a more extended acquaintance of the physicians here.

The society at its first session listened to an interesting demonstration of specimens of myocarditis segmentaire and of a blood cyst of the aortic valve, by Dr. Henry Douglas, of New York City. Dr. Weber then demonstrated specimens of blood of leukemia and pernicious anemia, and talked of the value of Ehrlich's method of blood-staining. Dr. Daland talked about malaria and relapsing fever in Russia, and demonstrated the pathological micro-organisms of these diseases. An interesting discussion of these papers followed.

Drs. Fitzgibbon and Mead, of Wisconsin, and Navy Surgeon Kenyoun, were present as visitors. Prof. Miller then offered the use of the Dental Lecturing Room of the University, Dorotheenstrasse 40, as a permanent meeting room for the society.

New-comers and others desiring information will please apply to or address the Secretary, Dr. Fredk. R. Weber, Charité, Berlin.

Golden Belt Medical Society.

The regular quarterly meeting of the "Golden Belt District Medical Society" for the annual election of officers, and mutual entertainment of the profession, will be held in the club-rooms of the National Hotel, Topeka, Kansas, April 9, 1891.

The large attendance in the past bespeaks a thriving condition of the Society, and a large attendance is desired at this, our most important meeting of the year.

The programme provides, for the afternoon session: A Report of a Case of Nymphomania with Treatment, by L. R. King, M. D., Junction City; A Report of Some Cases of Cystitis with Treatment, by J. H. Garey, M. D., Wilsey; Report of a Case (not described) by C. H. Guibor, M. D., Topeka.

For the evening session: A paper on Some Recent Improvements in Intestinal Surgery, with Demonstration upon the Dog, by Emory Lanphear, M. D., Kansas City, Mo.; one on Phimosis, Local and Remote Results, by A. H. Cordier, M. D., McPherson; one on Peri-Uterine Inflammation, by Chas. W. Adams, M. D., Kansas City, Mo., and the Annual Address by the President, P. Daugherty, M. D., Junction City.

The officers of the Society are: President, P. Daugherty, M. D., Junction City; First Vice-President, W. N. King, M. D., Abilene; Second Vice-President, Z. T. Harvey, M. D., Council Grove; Secretary, F. B. Browne, M. D., Salina; Treasurer, T. N. Gunn, M. D., Chapman.

State Board of Medical Examiners.

The Regents of the University of New York have appointed State Boards of Medical Examiners as follows:

From the Medical Society of the State of New York: for three years from September 1, 1891, W. W. Potter, of Buffalo, William S. Ely, of Rochester, and Maurice J. Levi, of Albany; for two years from September 1, 1891, William C. Way, of Elmira, and George R. Fowler, of Brooklyn; for one year from September 1, 1891, J. P. Creveling, of Auburn, and Eugene Beach, of Gloversville.

From the Homœopathic Medical Society of the State of New York: for three years from September 1, 1891, William S. Searle, of Brooklyn, Horace M. Paine, of Albany, and Asa S. Gosh, of Fredonia; for two years from September 1, 1891, John McE. Wetmore, of New York, and Jay W. Sheldon, of Syracuse; for one year from September 1, 1891, E. E. Snyder, of Binghamton, and A. R. Wright, of Buffalo.

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion."—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **C. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years.
Pronounced by connoisseurs unsurpassed for excellence and bouquet.

FRED'K DE BARY & CO., New York,

SOLE AGENTS IN THE UNITED STATES AND CANADA.

SANITAS

ANTISEPTICS, DISINFECTANTS AND OXIDANTS.

"Sanitas" is prepared by Oxidizing Terpene in the presence of Water with Atmospheric Air.

"SANITAS" DISINFECTING FLUID.

An aqueous extract of Air-Oxidized Terpene. Its active principles include Soluble Camphor ($C_{10}H_{16}O_2$), Peroxide of Hydrogen, and Thymol. Invaluable to the physician for internal or external application.

"SANITAS" DISINFECTING OIL.

Air-Oxidized Terpene. Its active principle is Camphoric Peroxide ($C_{10}H_{16}O_3$), a substance which produces Peroxide of Hydrogen when placed in contact with water or moist surfaces (wounds, mucous membranes, and other tissues). It is a powerful germicidal and oxidizing agent. For fumigations and inhalations in the treatment of diseases of the respiratory organs the oil only requires to be evaporated from boiling water.

"Sanitas" is Fragrant, Non-poisonous, and does not stain or corrode. It is put up in the form of FLUIDS, OIL, POWDERS AND SOAPS.

For Reports by Medical and Chemical Experts, Samples, Prices, etc., apply to the Factory,

636, 638, 640, and 642 West 55th Street, New York.

FRELIGH'S TABLETS,

(Cough and Constituent),

FOR THE PREVENTION AND CURE OF

PULMONARY PHTHISIS.

FORMULÆ.

Cough Tablets.

EACH TABLET CONTAINS.

Morph. Sulph. ($\frac{1}{60}$ gr.), Atropiæ Sulph. ($\frac{1}{100}$ gr.), Codeia ($\frac{1}{20}$ gr.), Antimony Tart. ($\frac{1}{25}$ gr.), Ipecac, Aconite, Pulsatilla, Dulcamara, Causticum, Graphite, Rhus-tox, and Lachesis, fractionally so arranged as to accomplish every indication in any form of cough.

Constituent Tablets.

EACH TABLET CONTAINS.

Arsenicum ($\frac{1}{60}$ gr.), Precipitate Carb. of Iron, Phos. Lime, Carb. Lime, Silica, and the other ultimate constituents, according to physiological chemistry (normally) in the human organism, together with Caraccas. Cocoa and Sugar.

PRICE, THREE DOLLARS PER DOUBLE BOX.

Containing sufficient Tablets of each kind to last from one to three months according to the condition of the patient.

SPECIAL OFFER.

While the above formulæ have been in use, in private practice, over 30 years, and we could give testimonials from well-known clergymen, lawyers and business men, we prefer to leave them to the unbiased judgment of the profession with the following offer: On receipt of 50 cents, and card, letter-head, bill-head, or other proof that the applicant is a physician in active practice, we will send, delivered, charges prepaid, one of the regular (double) boxes (retail price, Three Dollars), containing sufficient of each kind of Tablets to test them three months (in the majority of cases) in some one case. Card, letter-head, or some proof that the applicant is a physician in active practice, MUST accompany each application. Pamphlet, with full particulars, price-list, etc., on request.

As we furnish no samples through the trade, wholesale or retail, for samples, directions, price-list, etc., address,

I. O. WOODRUFF & CO.,

MANUFACTURERS OF PHYSICIANS' SPECIALTIES,

Clinical Lecture.

A CLINICAL LECTURE ON SOME EVERY-DAY CASES OF DISEASES OF THE EYE.[1]

BY HOWARD F. HANSELL, M. D.,
CHIEF OF CLINIC.

Occlusion of Canaliculi.

Gentlemen: The Professor of Ophthalmology in unavoidably absent to-day, and has requested me to occupy his hour.

The first case is one of acquired occlusion of the canaliculi. The patient lost her right eye through scarlet fever at four years of age. She presented herself at this clinic several weeks ago, to consult us as to the advisability of wearing an artificial eye. Upon examination it was found that the commissure of the lids had been shortened by an obliteration of the inner canthus. The eyeball was atrophied, reduced to nearly one-half the size of its fellow and slightly painful on pressure in the ciliary region. She was advised that an artificial eye might light up an already smouldering inflammation and induce sympathetic ophthalmia; moreover the eye was hopelessly blind and unsightly. The ball was enucleated in your presence by Prof. Thomson. Healing progressed favorably. A few days later the inner canthus was restored to its normal size by a plastic operation, but the canaliculi were replaced by cicatricial tissue. She now wears a glass eye and is greatly improved in appearance, but complains of constant overflow of tears. With a Graefe knife I now divide the cicatrix over the obliterated lower canal, thrusting its point inward as far as the nasal bone. With a probe the opening is enlarged. The latter process must be repeated several times during the next week, to prevent the walls of the new canal from growing together.

[1] Delivered at the Jefferson Medical College Hospital, January 16, 1890.

Stricture of the Lachrymal Duct.

This patient makes the same complaint we heard in the preceding case, but here the epiphora is due to a closure of the duct in one or more places by inflammatory thickening of the mucous membrane which lines it. Its cause might be found in some co-existing nasal catarrh or hypertrophy of the nasal mucous membrane, but frequently we are at a loss to establish a cause. As in the former case, I insert the point of a Weber's knife into the lower puncture, thrust it along the canal until it reaches the sac, and elevate the handle, thus making the canal a gutter. I then pass the knife down though the duct, dividing the stricture. This must be followed through several weeks by probing.

Lachrymation is a symptom or an accompaniment of many eye diseases, such as conjunctivitis, keratitis. Chronic lachrymation, or a constant overflow of tears, is unusual, unless as a symptom of chronic conjunctivitis, an everted lower lid or closure of the lachrymal canal. In the last condition only do we resort to the above operation. In old cases collection of pus and muco-pus constantly form in the sac, and are easily expressed. In such cases no doubt as to the diagnosis can exist. The result of the divulsion of the stricture either by knife or probe is not always favorable. Indeed I venture to assert, that few operators have been satisfied with their experiences. The treatment is painful, long continued and often unsuccessful, so that, as a final resort, a canulated silver style must be worn.

Soft Cataract.

The next case is one of soft cataract. This patient was treated by me several years ago for iritis serosa with dense vitreous opaci-

ties in the left eye without success. A cataract developed in the interval, and he now returns to have it removed. He is only twenty-five years old. Therefore, although the cataract is mature, the lens is soft and cannot be extracted according to the method pursued in the treatment of cataracts recurring after the age of forty or thereabouts. It must be needled, and usually more than once. While this procedure is extremely simple, it is not unattended with danger. Some of you may remember a similar case last winter in a healthy man, aged 25, who suffered with congenital cataract. After needling, glaucoma developed, and notwithstanding sclerotomy and iridectomy we were compelled to enucleate the ball on account of the dangerous condition to which the man was reduced, having lost twenty-five pounds in two weeks. I have warned this patient of the dangers and given rather an unfavorable prognosis, in view of the preceding inflammation, and he is willing to take the chances. The ball is free from injection, light projection is good and temperature is normal. I introduce a stop needle half-way between the centre of the cornea and its periphery, into the pupil dilated with atropine, and thrust it into the lens. By moving the point of the needle in various directions the lens is broken up and protrudes into the anterior chamber through the ruptured capsule. If the wound in the capsule remains open, the cataract will become absorbed; if not, the operation must be repeated.

Blindness from Neglected Iritis.

The next case is one of great interest, and I would ask you to give it your particular attention. Mary N., thirty years old, is nearly blind in both eyes from the effects of old iritis. In order that you may have a clear idea how this sad condition has resulted from an inflammation, which under proper and timely treatment would have been cured, please follow me closely in the brief consideration of the pathological changes that have here taken place. Inflammation of the irides, probably of syphilitic origin, developed two years ago, leaving the vision considerably obscured through exudation into the pupils. The papillary margins became totally adherent to the lens capsules, closing the channels of communication between the posterior and anterior chambers, compelling retention of normal secretion in the posterior chambers with consequent enlargement of those chambers by bellying forward of the irides and closure of the angle between the iris and the cornea. The adhesions or posterior synechiæ have been constant causes of recurring attacks of iritis, each of which caused still further deterioration of vision. To-day we find the ciliary vessels injected, the anterior chambers shallow, the pupils almost occluded, the fields of vision concentrically limited and central vision greatly deteriorated. Secondary glaucoma is threatening and will certainly develop unless the channels of communication are re-established by an iridectomy in each eye. I find the operations difficult, on account of the firm posterior synechiæ, but I am gratified to see that the new pupils are clear, the exudation being confined to the papillary margins.

This case conveys two important lessons to you as future practitioners. In iritis, keep the pupils dilated by means of frequent applications of strong solutions of atropine; in circular or annular synechiæ perform iridectomy.

Internal Strabismus.

I have to show you, lastly, a case of internal squint. As you are aware nine-tenths of all cases of this affection are the result of hypermetropia, and in most of them one eye is amblyopic. This patient has hypermetropia and astigmatism, which have been corrected during paralysis of accommodation. The vision of one, the fixing eye, improved to normal. The other, the squinting eye, to one-fifth only. The operation is undertaken chiefly for cosmetic purposes; for although the axes of vision should be made parallel, I have no anticipation of improving the vision in the amblyopic eye. By careful division of the conjunctiva of the tendon at its attachment to the sclera, and of the tendinous fibers which sometimes form broad lateral attachments, the effects of the operation may be safely regulated; and hence I always prefer in both high and low degrees of apparent abnormal convergence to operate on both internal recti. I will carefully sever each tendon, using the small hook, suggested by Stevens, rather than the large one commonly employed.

—Arecoline, the volatile liquid alkaloid of the areca nut principally affects the heart. It is excreted unchanged.

COMMUNICATIONS.

CONSTRUCTION AND ADAPTATION OF SPECTACLE-FRAMES.[1]

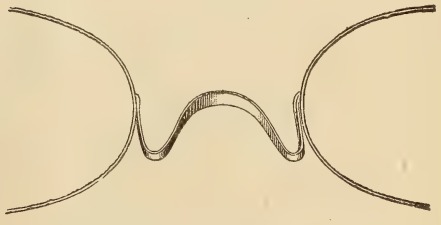
BY CHARLES HERMON THOMAS, M. D.,
PHILADELPHIA.

The treatment of ocular defects by means of glasses involves, beside the optical correction, a factor of no less practical importance —their mechanical adjustment. The purpose of the present paper is to direct attention to some of the mechanical aspects of the subject, particularly to the principles involved, and to certain methods of mounting spectacle-glasses. The results of the most accurate refractive measurements may be entirely vitiated by a faulty position of the correcting glasses; not only so, but new sources of eye-strain may be created by the very means adopted to remove an existing fault. Correcting glasses are remedial agents, just as orthopedic appliances are, and, as such, are powerful for evil as well as good, and hence everything belonging to them falls within the duty of the prescribing physician. The optical centre of a lens is generally that part of the glass which we wish to bring before the pupil, as it and the part of the lens immediately surrounding it are freest from aberrations of all sorts—distort least. Occasionally, however, it may be desirable to displace this point by a definite amount; in any case, we should insist on having the optician carry out our directions as regards the manner of mounting and the position of the glass with the same exactness that he employs in making it of the proper strength.

The purpose of the spectacle-frame is to hold a pair of glasses before the eyes in a definite position and with the least possible annoyance to the wearer. To accomplish this, I devised a plan about thirteen years ago (1878) for the construction of spectacle-bridges, which plan provides especially for a wide range of adaptability and the consequent accurate adaptation of spectacles to individual faces of almost every conceivable form. No account of the principles involved has heretofore been published, so far as is known, although some special forms of the bridge, as originally made under my direction, have come into almost universal use, being known throughout the optical trade under the name saddle-bridge.

Previous to the introduction of this bridge it was not practicable to obtain spectacle-frames suitable for persons with unusual forms of nose or face or with excessively prominent eyes or long lashes. Then, beside the ordinary "regular bridge," there was nothing better in use than the "X-bridge" or the equally unsatisfactory "snake-bridge," in both of which the combined weight of the glasses and frames was often borne directly upon the crest of the nose, besides which they usually failed to place the glasses in the correct position before the eyes. Few could wear either of the latter with comfort, and those who succeeded often did so only by padding them with wrappings of thread, thus making an unsightly cushion at the point of contact with the nose. The bridge (Fig. 1) under the plan

FIG. 1.



Saddle-bridge—typical form (back view).

referred to consists of (1) a nose-piece of arched form, of flattened wire and made to conform accurately to the shape of the nose at a definite point of selection, crossing the bridge of the nose at right angles and so resting saddle-wise upon it—whence its name. (2) A pair of adjustable return-pieces or arms, to the extremities of which are attached the rims or clasps carrying the glasses. These arms are produced by bending outward upon themselves the limbs of the wire from which the arch of the bridge has been formed, and are given whatever special direction may be required to place the glasses in the desired position before the eyes of the individual wearer. The bridge consists, then, of an arch and two adjustable arms, which, while fixing the glasses in their proper position before the eyes, should furnish as nearly an immovable support as possible.

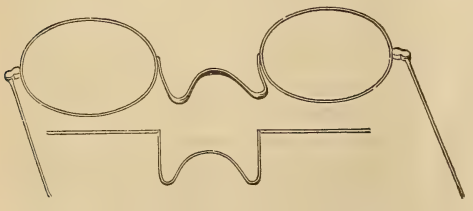
The bridge of the nose close to its root being the basis of support, the spectacle-bridge must be constructed with reference to this part. The wire of which it is made

[1] Read before the Philadelphia County Medical Society, February 11, 1891.

should be wide at the middle and taper towards each end, so as to make the bridge widest where it takes its bearing on the sensitive part of the crest of the nose. Narrowing the extremities is of special advantage, as it facilitates any necessary bending at that point in the process of adjustment. The sides of the arch should embrace the nose snugly without undue pressure, and extend well back towards the inner canthus, but not far enough to press upon the lachrymal sac. The saddle, or arch, as thus described, becomes the fixed support when it rests in its proper position. This position varies considerably in different persons, though on every nose there is usually one best point which should be sought—the point of selection, it may be termed. Unless the arch be adjusted to this particular point, the wearer will be rendered uncomfortable, and be continually shifting his spectacles. A few days' wear may be required to determine this point definitely in a particular case. The arch of the bridge, when once adapted to the nose, is not to be altered in position during any subsequent regulation or adjustment which may be required; it is to be considered as a definitely fixed support, whose situation is determined, once for all, by the conformation of the wearer's nose. Hence the position which the lenses are to take before the eyes does not directly depend upon the arch, but rather upon the length and direction of the adjustable arms attached to it, by variations in which the glasses may be made to take any required position. The arms are to be made long or short, they may be set high or low, pointed inward or outward, according to the requirements of any given case.

If the eyes be specially prominent, and the bridge of the nose be low, thus causing

Fig. 2.



Saddle-bridge, with horizontal arms; for prominent eyes and long lashes.

the lashes to project beyond the level of the nose, the arms must be made relatively long (Fig. 2); or if the bridge of the nose be low or flat, and the eyes be placed relatively high it may be required to direct the arms perpendicularly upward (Fig. 3); or again, if the bridge of the nose be prominent, and the eyes sunken, the arms should be shortened, or even reduced to the minimum required for purposes of lateral and vertical adjustment.

Fig. 3.

Saddle-bridge, with vertical arms for flattened nose; eyes high.

The height of the eye as related to the part of the nose on which the arch rests—the point of selection—determines the amount of slant, if any, to be given to the arms. In practice it is found that in by far the larger proportion of cases the arms are nearly horizontal, slanting slightly upward; in exceptional cases they slant downward below the horizontal; and in rare instances it is necessary to give them an almost perpendicular direction upward. The angle which the arms make with the clamp or rim carrying the glasses must vary according to the directions of the arms, in order to keep the plane of the glasses perpendicular to the visual lines. The arm, where it is soldered to the rim, or the clasp of frameless glasses, is slightly bent in an upward direction. Increasing or diminishing these curves changes the position of the glasses vertically, and so compensates for any degree of upward or downward slant of the arms. This may be necessary where, for example, the point of selection of the arch is low down on the nose; the arms must then ascend vertically to raise the glasses to a level with the eyes; but this position of the arms will cause the glasses to assume an approximately horizontal direction—parallel to the visual lines—if the arms meet the rim at or about a right angle, as they usually do; in such a case, the arm must be bent so as to join the lens at an oblique angle or even lie in the plane of the lens.

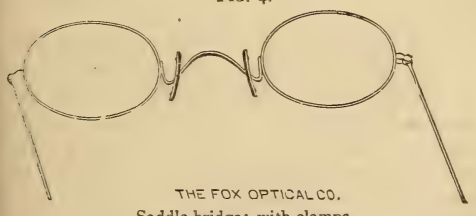
The proper adjustment of a pair of spectacles in ordinary cases is largely determined, as we have seen, by the length and direction of the arms. In special cases, also, as in asymmetry of the face, the compensation required is to be effected by the same means. In some cases the arms may need to be of unequal length. It is of frequent occurrence

that the centres of the pupils on the two sides are unequally distant from the centre of the arch. When this condition exists it is to be met by varying the direction and, it may be, also the length, of the arms. It is important from the point of view of the optician, to note that the principle adaptations of the bridge are preferably to be made extemporaneously and with the patient present. In this way, with a variety of sizes of the typical form at hand, the skilful mechanic is able to produce any particular modification which may be required without specially constructing the frames, even for atypical faces. It is often desirable to take the conformation of the nose at the point of selection. This may conveniently be done with lead wire, and the outline thus obtained may—by "rubbing"—be made a part of the record of the case.

Variations in the size of the lenses employed will also necessitate modifications in the lateral adjustment of the arms. To get the advantages of a large glass in cases where the distance between the eyes is relatively small, the arms will have to be bent inward—made to approach each other. The opposite direction may have to be given them in cases of unusual width of face. Lateral supports, or clamps, which take their bearing lengthwise on the sides of the nose near the base, as in eye-glasses of the best construction, have occasionally been employed by others in combination with spectacle-frames, but usually in form and by mechanical means not wholly satisfactory.

I have recently had made by the Fox Optical Company a combination of the eye-glass clamps with the saddle-bridge (Fig. 4), which is neat and simple in construction,

Fig. 4.

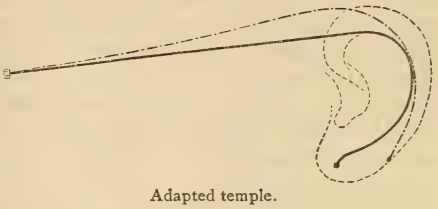


Saddle-bridge: with clamps.

and which combines the advantages of both in great degree. The attachment is so made as to preserve the adjustability both of the bridge and the clamps. The special advantage of this combination is that it distributes the pressure over a larger surface, and upon parts better able to sustain it than does the arch of the bridge alone.

The side-pieces, or temples, should be specially adapted to the ear with as much care as the bridge is to the nose in each individual case. They should be hooked around the ears for constant use and be so formed as to retain the bridge at the point of selection on the nose, and thus secure a fixed position of the entire appliance. The

Fig. 5.



Adapted temple.

curve of temples, as ordinarily made, is of far too great a radius. It takes its bearing behind the ear upon a limited surface, and so is liable to cut; it fails to secure a proper hold to prevent its riding upward, and it often exerts spring-pressure productive of pain and injurious to ears and nose alike.

An adapted temple, designed to fulfil the above indications and obviate these defects, has recently been constructed under my directions, and has borne the test of use so well as to justify its continued regular employment (Fig. 5). The wire of which it is made passes back in a straight line to the top of the ear, at which point it is bent somewhat abruptly downward, and is made to conform accurately to the posterior surface of the conch close to its junction with the head, where it rests in contact with the ear, but without perceptible pressure. Asymmetry in the height of the ears, causing tilting of the frames from the level, is to be met by a compensating adjustment in the temples, *i. e.*, bending the temple upward on the side of the higher or downward on the side of the lower ear—or both—and so dividing the result between the two sides.

The glasses should be slightly inclined from the perpendicular, so as to bring the lower edges somewhat nearer the face than the upper, which is to be effected by giving the temples the appropriate angulation at their junction with the hinges when it is impracticable to change the direction of the hinges themselves.

The material of the frames should usually be gold of a good quality and of a weight as light as is consistent with strength and steadiness. Steel rusts too readily and is

not well adapted to the adjustments frequently required—more especially in the temples. Silver is so soft as to be almost worthless.

The lenses themselves should usually be as large as the face of the wearer permits: seldom less than 28x38 mm. for an adult, and not infrequently as large as 29x40 or 30x42 mm., in order that the eyes may be well covered in their ordinary lateral movements. Such large lenses are hardly more conspicuous than small ones—especially if frameless glasses be used—because they allow the eye itself to be easily seen. The reflections from the edges of frameless glasses which are so annoying to some persons may be avoided by slightly dulling the polish on the lower edge; the source of this reflected light being usually at or above the level of the eyes, the reflection enters the eye from this edge alone.

The glasses should be worn as close to the eyes as possible, without touching the lashes. Occasionally, where the lashes are especially long, with feathery or uneven ends, they should be neatly trimmed with the scissors—a little procedure best practiced when the eyes are closed. It is also to be borne in mind that the subject has an artistic aspect and that by giving proper consideration to this phase much can be done to remove the opprobrium which frequently attaches to the wearing of glasses. The neat adjustment of a pair of frameless gold-mounted spectacles is doubtless the best that can be accomplished with spectacles in this respect.

I have limited myself to a description of no one form of bridge, nor even of a number of special forms, but the effort has been made rather to demonstrate *the mechanical principles involved in the construction and adaptation of spectacle-frames suitable to all the requirements of practice.* By the means proposed it is practicable to secure the correct position of the glasses before the eyes, together with comfort to the wearer and a satisfactory artistic effect, thus fulfilling the three principal indications of spectacle-mounting.

UNUSUAL CASE OF PELVIC ABSCESS.

BY ALEXIS M. LÉON, M. D.,
NEW YORK.

A collection of pus in the cavity of the pelvis may be the result of one or more distinct inflammatory processes. Primarily the cause may be (1) an injury, (2) a tubercular process, (3) a suppurative inflammation occurring in an ovarian tumor for hæmatocele, or (4) a puerperal infection.

Again, its seat may be (1) in the connective tissue of the broad ligaments, (2) in the general cellular tissue of the pelvis, or (3), as a result of peritonitis, it may be enwalled by peritoneum. A pyosalpinx might also be considered a form of pelvic abscess.

By far the most frequent form of the disease under consideration is a cellulitis of the broad ligaments due to puerperal infection. Authorities have not considered, however, that the variety or seat of the inflammation in the pelvis has much to do with the symptoms or course of the disease. The diagnosis, it is believed, can be easily made by the symptoms of septicemia and the physical signs of the existence of a tumor in the pelvis. The termination of the cases, if left to Nature and if the patient survive the septicemia, is said to be in the discharge of the abscess either (1) "through the abdominal walls and saphenous openings, (2) into the pelvic viscera, as the bladder, rectum, vagina or urethra, (3) through the floor of the pelvis near the anus, (4) through the pelvis foramina, either obturator or sacro-ischiatic, (5) through the pelvic roof into the peritoneal cavity or (6) into the lumbar region in the position of the kidney." (J. Braxton Hicks.)

This general view of pelvic abscess embraces both the common and unusual forms of the disease. The cases presenting, together with marked constitutional symptoms, a palpable abscess in the pelvis, which, in a short time discharges or is relieved by operation, are of comparatively frequent occurrence. But the cases wherein the diagnosis is difficult, and no tumor or swelling is discoverable by examination are rare. Yet, probably, both classes are produced under the same conditions, and are originally located in the same parts of the pelvis. The interest in these latter cases, therefore, lies in the fact that occasionally a collection of pus, due to any of the causes of pelvic ab-

scess, may reside in the pelvis and escape detection. And this fact does not seem to have been very generally stated.

The following case illustrates this difficulty in diagnosis. It is unique, also, in its chronicity, its spontaneous cure, in the uncertainty of its seat of origin and in the course or directions of the burrowing of the pus.

The patient, 29 years old, a native of Italy, married and the mother of four children, was a stout and strong woman, whose family history was good and who never remembered having been sick, with the exception of an attack of scarlatina some years before. Two years ago she had resided in a malarial district. Her last child was born April 8, 1888. Her labor was managed by a midwife, and is said to have been easy and natural. During the last months of her pregnancy, however, she had not felt perfectly well. She was languid, complained of headaches and had noticed slight puffiness about the face and ankles. After her labor all progressed favorably until the third day, when, it is said, fever set in. On April 16, eight days after the confinement, I saw the patient. At this time she complained of feverishness and loss of appetite; the bowels were loose; she was having two or three watery passages per day, and there was a profuse inodorous white discharge from the uterus. Temperature, 104°; pulse, 120; respiration, 30. She complained of no pain and there had been no vomiting.

Examination of the heart and lungs was negative, except that a few râles were heard at the bottom of the chest, posteriorly. The liver was not enlarged; the spleen was somewhat enlarged. Some tenderness was found, on deep pressure, over the fundus uteri and to the left of it. The uterus itself was subinvoluted and the cervix was lacerated. By conjoined manipulation, no particular tenderness and no tumor could be determined in the broad ligament or in any part of the pelvic cavity. The uterus was freely movable, and movement did not cause pain.

On the following day there was amelioration of the symptoms. Temperature, 102°; pulse, 110. The discharge still continued—profuse and inodorous, and the patient declared she felt no pain. During the three days following the improvement progressed. On April 20, examination showed the uterus to be much smaller in size. The tenderness had disappeared and the discharge had ceased abruptly. The fever continued, however, together with the diarrhœa. The movements from the bowels were large, watery and bad smelling. The temperature varied from 100½° to 101½° in the morning, from 102½° to 103½° in the evening, when profuse sweating would set in, often lasting through the whole night. Occasionally in the afternoons the patient would complain of chilly sensations; though no marked chill occurred. She now became emaciated and markedly anemic. Anorexia was complete; so that nourishment was given with difficulty. The urine was slightly albuminous and showed a few granular casts and renal epithelia under the microscope. This condition of the patient persisted during the next three weeks with but little change. The temperature gradually sank; so that by the end of this time it did not rise above 100° in the morning, or above 101° in the evening, and was sometimes lower; and the pulse-rate fell correspondingly. Antipyretics, it may be stated, had little or no effect, however. The sweatings, too, became less frequent and of milder character. Digital examination showed the uterus to be of normal size and in proper position, freely movable and its movements free from pain. No tumor could be found in the pelvis, and no tenderness was elicited by bimanual touch. The result of rectal examination with the finger was also negative.

By May 15, the albumin and casts disappeared from the urine and the morning temperature fell as low as 99°. The patient made efforts to sit up, but was unable to remain out of bed. Under treatment the anemia became less marked and the appetite began to return; so that occasionally she could eat a little solid food. She did not gain strength, however.

About May 23 she called attention to a stiffness and pain in the left groin. This was occasioned by straightening out the leg. There was no swelling or redness about the parts and no tenderness either about the abdomen or leg. The thigh was kept partially flexed and rotated inwards, and the pain made it impossible to fully extend the leg. When standing or attempting to walk, the pelvis would be tilted to one side and only the toes of the left foot would touch the ground. The amount of pain and stiffness and the flexure of the thigh varied from day to day. On June 5, careful examination (which had been employed daily since the appearance of the symptoms about the leg) revealed some fulness in the left

lumbar region, but no fluctuation. Deep pressure over this spot caused some pain. This swelling increased during the next four or five days and could readily be mapped out—about four inches in diameter, not projecting far outwards and causing no discoloration of the skin.

It was proposed to introduce an aspirator needle, and if pus were withdrawn to cut down upon the needle and drain the abscess. The patient would not consent to any surgical procedure and even refused to be aspirated. On this account the case was out of observation from the 11th to the 25th of June. On this day the patient's general condition was found to be about as before. The swelling in the back had increased somewhat, and external to the quadratus lumborum. The skin was red and the tissues hardened and infiltrated. This redness extended slowly forwards from day to day along the abdominal wall, in a line parallel to the crest of the ilium, until the groin was reached. The skin here became thin and on July 3 opened, giving vent to about one quart of thick yellow pus, which continued to flow in large quantities for several days. Again the patient refused surgical aid and would not allow even probing of the sinus. At this time her fever disappeared, her diarrhœa stopped, her appetite returned and the flexure of the thigh began to grow less and less. The abscess continued to discharge for three or four weeks. From its situation it drained itself, and so was completely cured in that time. The patient grew strong and well and the flexure of the limb, after a while, entirely disappeared, allowing the patient to stand perfectly straight and to walk without difficulty. On June 25, 1889, she was delivered of a healthy child, after a normal labor.

It will be observed in reviewing this case, that distinct signs of pelvic inflammation occurred at no time except during the first few days, when the discharge from the uterus was present, and the signs were, then, more of endometritis than of cellulitis; that the abscess was probably in existence six weeks without presenting any local signs, such as pain, tenderness, swelling etc., and at the end of this time the only sign was the flexure of the thigh and the pain on effort of extension; that it was two weeks longer before the fulness in the lumbar region occurred, and two weeks longer still before the skin showed positive evidence of the inflammatory process beneath it; and that it was nearly three months in all before the abscess was discharged. These general features may explain why the diagnosis was not made positive until the appearances in the loin presented themselves. Previous to this time the picture was one of continued fever with diarrhœa, and more or less septic infection; and it was recognized that such condition might be produced by typhoid fever, acute miliary tuberculosis, or an abscess causing pyemia.

It should be stated that this patient was several times examined by different consultants, without their being able to locate any lesion in the pelvis, notwithstanding the fact that attention was directed at first to the pelvis as the seat of the disease and repeated efforts were made to find an abscess whose existence was suspected. The question of the exact location of the primary abscess is, on this account, not settled with certainty. It is likely, however, that its seat was in the left broad ligament. Its small size in the beginning, together with the fact that its contents, were drained through the uterus, would explain why no tumor could be appreciated. And there must have occurred early in the history of the case adhesions between the abscess and the posterior wall of the pelvis as high up as the brim, and perhaps higher. In this manner the tumor, as it grew in size, was pulled further and further out of reach by any ordinary examination; though it is possible that examination by the introduction of the hand into the rectum might have given some idea of its existence. It is conjectured, therefore, that the abscess began in or near the fimbriated end of the Fallopian tube—since, in this location, it could discharge through the tube (as it seemed to do at first) and, being movable, could form adhesions posteriorly.

Cases similiar to this one are reported by Dr. Skene, in his text book of *Diseases of Women*, and reference to them may supply the actual appearances presented by dissection. Dr. Skene relates these as cases of "pelvic cellulitis, with certain complications which, so far as I know, have not been noticed or described heretofore." The first patient, 37 years old, and the mother of six children, got up the fifth day after confinement, and was taken sick on the ninth day. She was in bed, but without medical attendance for six weeks, when she was seen by a physician who found all the signs of pelvic cellulitis of the left broad ligament and symptoms of septicemia. Four weeks later

she was admitted to the hospital for operation. She was then in a very enfeebled condition, her temperature varied from 100° to 103°, and there was flexure of the left thigh. The abdominal symptoms had subsided. Laparotomy was done by Dr. Skene, "and a most careful exploration of the pelvis was made by the touch. The left broad ligament was considerably thickened and much less elastic than it should have been, showing the effect of the inflammation, which had subsided. Not the slightest sign of any point of suppuration could be found, but by the bimanual touch, with the fingers of one hand in the abdominal cavity and those of the other on the outside, I detected obscure fluctuation, indicating that an abscess or sinus extended along that side of the abdomen. The location of the pus having been clearly marked, the wound in the abdomen was closed and an incision made in the side down to the pus." The cavity, which was narrow at its lowest end, was found to extend to the diaphgram. It was washed out and a drainage-tube was introduced. The patient passed out of observation one month after the operation; at which time the wound was still discharging pus.

The second patient, 35 years old, gave a history of illness (fever) from the day of the birth of her fifth child. She was seen four months after confinement, when symptoms of septicemia were present, and there was also flexure of the right thigh. The uterus was apparently normal and movable, but high up and on the right there were evidences of inflammatory products. Explorations with the aspirator failed to discover pus. Laparotomy was performed, and pus was found in the right iliac and lumbar regions. The patient died three days later. "The autopsy showed that the abscess cavity extended from the right broad ligament upward behind the kidney and to the right of the spinal column to the diaphragm. The psoas muscle was involved in the abscess, but there was no bone disease, and it was the opinion of all who attended the autopsy that the disease began as a cellulitis of the right broad ligament."

These cases resemble the one I have the privilege of reporting in the following points. All began (probably) as a localized cellulitis of one broad ligament; sooner or later adhesions were formed between the abscess and the posterior pelvic wall; and the pus, then, tended to burrow towards the surface through and between the muscles. The track thus made by the burrowing pus, it will be noted, tended to close up and heal as the sinus advanced; so that, by the time the site of the abscess was upon the psoas muscle, the suppuration in the broad ligament had ceased.

These cases are certainly rare (I have not found any others reported), and the lesson of special interest they teach is, that a pelvic inflammation may result in an abscess, which, even early, may occupy a position out of reach by any ordinary examination; and such a condition may be difficult of diagnosis.

DOUBLE OPTIC NEURITIS OF MALARIAL ORIGIN.[1]

BY FRANK W. RING, A. M., M. D.,
NEW YORK.

MEMBER OF THE NEW YORK ACADEMY OF MEDICINE; ASSISTANT SURGEON, MANHATTAN EYE AND EAR HOSPITAL, ETC.

January 12, 1888, Mrs. F. K. W., fifty-five years old, consulted Dr. C. W. Packard, of New York, on account of failing vision. The patient was referred to me. She complained of a blur in the upper field. Upon examination I found moderate peripheric impairment of the field in the left eye. Right vision $=\frac{20}{15}$ W. $+.75$. Left vision, $\frac{20}{20}$ W. $+1.0$. Ophthalmoscopic examination negative.

January 13. The following morning the patient was led to my office by a daughter. R. V. = 5 fingers; L. V. = perception of light. She had retired the preceding evening, seeing as well as when at my office in the morning, and awakened practically blind. Right field with candle, quick and good. Ophthalmoscope showed marked papillitis, œdema of the disc, evident infiltration in and near the optic nerve, veins slightly enlarged, no pulsation, arteries about normal, outline of disc somewhat obscure, slight tortuosity of veins, no retinal changes apparent. Approximate swelling of $3\frac{1}{2}$ dioptrics of nerve.

Thinking the case of unusual interest, I took the patient to Drs. Agnew and Webster. They corroborated my diagnosis and expressed surprise at the rapidity of loss of vision.

---

[1] Read before the New York State Medical Society, February 3, 1891.

January 18. Perception of light in each eye. January 22. V.=nil.

January 30. Sixteen days from beginning neuritis, complains of stiffness in knees. Has more or less difficulty in walking. When reclining, finds it impossible to turn over. This affection of the joints came on suddenly and in four days the patient could not rise from a chair without assistance. By being supported she could shuffle along the floor. On striking her quickly under the hip, the limb would fly up, and by this action she could ascend stairs. There was complete paraplegia. Exaggerated reflex, ankle clonus. In fact, she lost all locomotive power of the lower extremities. The skin felt thick and numb. Bladder unaffected.

February 5. Patient for the first time in fourteen days has perception of light. Has enough control of her limbs to enable her to move about with the aid of a chair.

February 22. Vision improving. R. V.= 10 fingers. L. V.=5 fingers. Color perception lost as far as could be ascertained. Six days later can distinguish bright red. Field good, retinal vessels slightly diminished in size.

March 7, 1889, thirty-nine days from beginning paraplegia, is able to walk. R. V.= $\frac{20}{200}$; L. V.=$\frac{4}{200}$. Field good, color sense diminished. Nerves pale, otherwise the fundi are normal, with the exception of slight decrease in caliber of arteries.

April 7, 1889. R. V.=$\frac{20}{40}$; L. V.=$\frac{20}{100}$. Color sense varies; calls red brown. Left nerve whiter than right.

April 17, 1889. Stiffness in knees entirely gone. Color perception impaired.

February 14, 1890, two years from initial papillitis, R. V.=$\frac{20}{15}$W.+.5 L. V.= $\frac{20}{20}$+W.+.5, which is a return to the original vision before the neuritis. Color sense decidedly impaired.

December 29, 1890, last examination and nearly three years from beginning neuritis, R. V. =$\frac{20}{15}$W.+.75; L. V.=$\frac{20}{20}$+W. +1.0. Ophthalmoscopical appearance: Rt. =nerve bluish white, veins normal, arteries slightly diminished; no tortuosity; lamina cribrosa plainly visible. Left=nerve bluish white, otherwise the fundus has a normal appearance. Color sense: pale yellow, green, or pink, looks drab; cannot distinguish green from blue. Right eye=the field for yellow is very much contracted. A little less for red, and less than normal for blue. Left eye=yellow visible in central vision only. Red, field tortuous in outline and very much diminished. Blue, contracted much less than in right, with a large scotoma in upper field. Field for white perfect in each.

The patient received a nutritious diet, iodide of potash, arsenic and strychnia.

During the entire illness, the patient was free from pain, slept well, appetite good, no nausea, no headache. The urine was examined several times, with negative results. No specific history. She has had eight children, all healthy, no miscarriages. Passed the climacteric at forty-two years. Mrs. W. has been a decidedly healthy woman, with one exception, and that exception is best expressed by the following extract from a letter written by Dr. Packard: "So far as I know, Mrs. W. has no specific taint, but she has a decided malarial taint. I have treated her during the past few years for several malarial attacks, accompanied with fever, characterized by periodicity, and that yielded to quinine. At such time she has suffered from gastralgia and enteralgia that I believed to have a malarial basis."

Résumé.—An apparently healthy woman consults an oculist because of a slight blur in her vision. He finds both fundi normal, pupils slightly dilated and responsive to light. During the same night she becomes practically blind. The only apparent cause is a marked papillitis. This continues to be an idiopathic affection for sixteen days, then she has a paraplegia. The vision becomes totally lost. In fourteen days, upon a relaxation of the paraplegic symptoms, the sight gradually returns; and in two years is normal, with a decided defect in color vision.

Was the neuritis an idiopathic affection, or was it concomitant to the paraplegia, and what was the existing cause of both?

Optic neuritis is often accompanied with headache, nausea and vomiting; and it usually occurs from some intra-cranial disease, tumor or other adventitious product.

With tumor the progress is inclined to be slow and the prognosis grave. To be brief, let us exclude tumor as a cause, also meningitis and sclerosis and Bright's, for palpable reasons.

Retro-bulbar neuritis (von Græfe).—A condition in which we may have a sudden loss of vision. The pupil is usually widely dilated and not responsive to light. The disc becomes slightly elevated. Arteries small, veins tortuous.

"In retro-bulbar neuritis in the acute form, we have headache, orbital pain, in-

creased by movement of the eye and pressure. Serous effusion of the optic disc and retina due to compression of retinal vessels." (Knapp.)

In Noyes's admirable treatise on the eye (1890) he describes a toxic retro-bulbar neuritis, where the atrophy succeeding the inflammation is due to a lesion of the axial fibers of the nerve, and cites a case of Uhthoff's, where he localizes the character of the lesion in color scotoma. If there is a retro-bulbar neuritis due to tobacco and alcohol poisoning, why may there not be a similar affection due to malarial poisoning?

There are certain affections due to the action of malarial poison upon the system. There is a *bacillus malariæ* particularly affecting the spleen. This bacillus has been found in the blood during the fever, causing marked changes in it.

Let us turn our attention to another cause of papillitis, denied by some, *i. e.*, distention of the sheath, or hydropsia of the optic nerve, which is a serous effusion into the optic sheath coming from the cerebral arachnoid space.

"A fluid effusion into the arachnoid space and increased intra-cranial pressure are always associated with an accumulation of fluid in the intra-vaginal sheath, which œdema will cause a swelling of the optic nerve." (Schwalbe.)

"The intra-cranial pressure must force the fluid from the arachnoid space along the sheath of the optic nerve into the canal-like system present in the lamina cribrosa, causing swelling and congestion of the disc." (Pagenstecher.)

Bull says, loss of vision from isolated papillitis alone is never sudden, and that distention of the sheath alone is not sufficient to produce papillitis, but may intensify it. Hughlings Jackson is of the same opinion, and the latter also says there is nearly always a visible stage of neuritis before sight fails.

Macnamara, in his text-book of disease of the eye, cites a case precisely similar in many respects to the one in question. A girl, aged thirteen, was attacked with intermittent fever, after which she had paralysis of the lower extremities, and a partial inability to move the right arm. Pupils dilated and insensible to light. Optic papillæ swollen and hazy, with serous effusion into the nerve and surrounding tissue. She became quite blind. Her recovery was gradual and perfect, both as to the paraplegia and vision. He remarks that this is an example of a class of cases not very uncommon in India, and depends upon malarial poison affecting alterations in the blood. He gave, as a direct cause, a serous effusion into the optic thalami and corpora striata. The pressure thus exerted on these nerve centres, interfering with the volition of the patient over the affected limbs, and the serous effusion or exudation into the papilla and pressure upon the optic nerve fibers causing the loss of vision.

I offer this paper as a contribution to the literature on optic neuritis. I am aware there may be double optic neuritis with and without loss of vision, also with gradual or sudden loss of vision. But, as a rule, there is a stage of neuritis visible before the blindness. Here the fundi were known to be normal a few hours before an almost total loss of sight.

101 Park Avenue.

ADHESION OF SOFT PALATE TO PHARYNX; OPERATION; CURE.[1]

BY HAL FOSTER, M. D.,
KANSAS CITY, MO.
LARYNGOLOGIST TO ALL SAINTS' AND MISSOURI PACIFIC R. R. HOSPITAL.

The patient, a man 40 years old, by occupation a seaman, and a native of France, applied to me November, 1889, complaining of shortness of breath. He wanted to know if anything could be done to restore his speech. He was able to utter a sound, but he could not turn this sound into words.

He had contracted syphilis twenty years before. He was married, and his wife had miscarried three times. One child was born living, and is now twelve years of age, and apparently in fair health. This communication was made on paper, as the patient was unable to talk. His nose was entirely eaten away down to the nasal bones, so that all that remained was a small opening in the face. The nasal fossæ would fill up with large green crusts, which he dislodged with a hair-pin every morning and evening. The stench from these crusts was exceedingly offensive. I took out two, which were fully ten and a half inches in length, and shell-like in form. The patient's mouth was so

[1] Read before the Medical Society of the Missouri Valley, December, 1890.

closed up by syphilitic adhesions that I could pass in my two fingers only with great difficulty, by stretching the mouth to its utmost capacity. A laryngoscopic view of the throat at this stage was impossible.

The first operation I undertook was enlargement of the mouth, which was done by means of a knife. Afterwards little wooden stretchers or gags were inserted, to prevent the wounded surfaces from growing together again. After this was accomplished, I found that the uvula and the lower part of the soft palate were entirely destroyed, and the remaining part of the palate was firmly adherent to the pharynx, so that the upper pharynx was completely separate from the lower pharynx. The complete occlusion of the two pharynges is extremely rare. I have met with it in only three cases. It is by no means rare in tertiary syphilis of the throat to find a partial adhesion of the parts; but it is extremely rare to find a complete adhesion. Often a small opening can be discovered, sometimes only large enough to admit a small probe, but still large enough to admit a small current of air.

In this case I covered the lower pharynx with iodoform and filled the nasal fossæ with water. My iodoform was not moistened.

I now determined to liberate the palate from the pharynx, so that I could give my patient nasal breathing, and also give the nasal cavity an outlet into the throat. I first passed a silver probe down through the nose to the pharynx, and with a tenotomy knife cut where the palate bellied. After I had thoroughly separated the palate from its attachment, with no little difficulty, the parts were sprayed with a solution of tannin. No anæsthetic of any kind was used. I now began to pass the largest sound I could obtain through the opening into the pharynx. I afterwards had a sound made after the following description. The body of the instrument was about two inches in length, and it was blunt-pointed at the end, and gradually as it reached the base, it was somewhat similar to a triangle in shape. The base was an inch and a half in width. To the broad end of the instrument was attached a long handle, so that it could be manipulated in the throat. I found that with this instrument I could keep the opening the required size and prevent it from closing. Had the wound not been treated with sounds after cutting, the opening would have filled up in a very short time.

This is a peculiar characteristic of syphilitic tissue, where we seek to enlarge an opening, whether it be in the pharynx or nasal fossæ. In a case of nasal stenosis now under observation, I have seen the parts close completely after opening the nasal canal three times, every time giving the patient complete breathing space, taking out at each operation a large piece of cartilage at the point of union. In a short time the parts were firmly adherent again.

The parts in this operation healed nicely, and within four days absolutely no pain was felt from the passage of the instrument. An examination of the larynx showed complete paralysis of the abductors of the vocal cords, and the whole mucous membrane lining the larynx was in a state of hyperemia. This accounted for the loss of voice. At the beginning of my operations, I had placed my patient under iodide of potassium; but I was compelled to give him 90 grains, three times a day, before I could produce any effect. I do not consider this an unusually large dose in cases of tertiary syphilis of the throat and nose, and have often given larger doses and maintained them during a longer time. This was given in Vichy water; his stomach stood it nicely, and I kept this amount up for two weeks, when it was gradually reduced. Later I gave him only tonic doses. Within a month and a half from the time of the first operation on the mouth, the patient had entirely regained his voice, and had gained something like fifteen pounds in weight. His voice was now quite clear and strong. I had an artificial nose made for him by Tiemann & Co., while I was attending the Manhattan Throat Hospital of New York last August, which supplied his missing member very well. I gave him one of the sounds above described, and told him to use it once or twice a week for a year. I often hear from him, and he reports the breathing through his artificial member excellent, and his voice good.

Syphilis from a Bite.—A patient was recently shown to the Berlin Medical Society with syphilis from the bite of a man. The bite was on the lip. The wound healed in two or three days; but in six weeks it reopened and the lip became greatly swollen. Five weeks later there was an ulcer on the inner surface of the lip with great swelling and induration round about; the submaxillary and cervical glands were much enlarged. After some time a typical syphilitic eruption made its appearance.

PERISCOPE.

Some New Medicinal Soaps.

In its Periscope of Dermatology, the *Edinburgh Medical Journal*, February, 1891, says: Eichhoff of Elberfield, who has already added to the list of medicinal soaps some of real value, and embodying some valuable improvements, has continued his researches into the subject. He reviews the conditions of the skin in which soap treatment is to be recommended. This is specially indicated in cases where the skin is unctuous. The soap removes the excess of fat, while the incorporated drug, if suitably chosen, acts at the same time on the disease itself, and, as Eichhoff thinks, can chase the offending organisms from the ducts of the cutaneous glands. He quotes in support of this the treatment by medicinal soaps of psoriasis, which he regards as parasitic, and of acne, the pustules in which are now believed to be due to the pyogenic micrococci. He praises also the cleanliness, the innocuousness, and the cheapness of this method with the vigor of a true partisan.

Soaps may be, for convenience, divided into—1. Alkaline, containing an excess of free alkali; 2. Neutral, in which all the alkali is combined with the fatty acids; 3. So-called acid soaps, which are prepared either by the addition of weak acids, or by being superfatted, and eventually react faintly acid. The alkaline may be used to remove masses of scales; while in acute inflammations of the skin, or when it is irritable, the neutral or superfatted soaps are to be employed. The superfatting of the new soaps consists of 2 per cent. lanoline and 3 per cent. olive oil, and they are made by Ferdinand Mühlens at Cologne. Among these new soaps may be specially mentioned a *menthol soap*, containing 5 per cent. of menthol. The local anæsthetic influence of menthol on the skin is well known, and the principal use of this soap will probably be found in lessening pruritus. Eichhoff cites some cases where cure resulted in pruritus senilis and pruritus genitalium. He recommends that, should the soap be employed for the head or face, the eyes should be kept firmly shut, else an unpleasant, though, he says, not dangerous, coldness of the conjunctiva is perceived. A 5 per cent. *salol* soap is one which may prove useful in psoriasis. The salol when so used with water breaks up into carbolic and salicylic acids, and these in their nascent condition may be expected to act with energy. A 5 per cent. *resorcin* soap promises to be of advantage in cases where this valuable drug is indicated.

Ligation of the Saphena Vein in Cases of Varicose Veins.

The *British Medical Journal* (Supplement), January 24, 1891, says: Professor Trendelenburg, of Bonn, in a contribution to the last number of the *Beiträge zur klinischen Chirurgie*, advocates double ligature and division of the large saphena vein in the treatment of varicosity of the lower limb involving both the trunk and branches of this vessel. In some remarks on the pathological anatomy of varicose veins it is pointed out that the most prominent and dilated portions of the affected vessel are found below, and not, as is generally supposed, (? REPORTER) above the valves. The walls of the vein, being weaker here than at any other point, yield to the pressure of the blood when the valves cease to act. According to Trendelenburg, most of the blood which fills the dilated trunk and branches of a varicose saphena vein is derived from above, and has descended from the iliac veins and the vena cava, and but a small portion of it comes from the capillaries of the foot and leg. When the subject of varicose veins exchanges the horizontal for the vertical position a large quantity of blood at once descends from the large veins of the abdomen into the dilated veins of the lower extremity. It is this free downward flow of blood along large and dilated vessels deprived of valves that causes the profuse and dangerous hemorrhage so frequently produced by a breach of the surface of the leg when in a condition of varicosity. The conclusion that the troubles and dangers of those suffering from varicose veins of the lower limb are due for the most part to the fact that the varicose branches of the great saphena, in consequence of associated dilatation of the trunk of this vein, are no longer separated from the vena cava by valves, has led Trendelenburg to treat varicosity by permanently obstructing the saphenous trunk at one point with the view of preventing the descent of blood from the abdomen, and thus relieving the veins of the leg and foot from the abnormal pressure. After obstruction of the flow of blood through the main trunk of

the great saphena, the venous circulation will be maintained by communicating branches between the superficial and deep veins. Reference is made to a series of cases in which good results followed such treatment, which consists in exposure of the vein near the saphenous opening, in the application of two catgut ligatures, and in the division of the vessel between them. It is acknowledged in this paper that occlusion of the great saphena is by no means a novel plan of treatment in cases of varicosity of the lower extremity. It was practiced by Paulus Ægineta, and advocated by Ambroise Paré, and at the end of the last century Sir Everard Home performed this operation on twelve cases with very unfavorable results.

Vaccination of Children.

Dr. E. F. Brush, in a paper on Infant Hygiene, read before the Jenkins Medical Association and published in the *Archives of Pediatrics*, February, 1891, makes some pertinent remarks on the subject of vaccination, saying that this important hygienic measure, if physicians are not more careful in regard to the operation, is liable to be brought into disrepute. In 1883, while Dr. Brush was occupying the position of attendant physician to the New York Infant Asylum, he examined the arms of one hundred and ninety-one children who had been vaccinated and deemed sufficiently protected. Of these he found only thirteen with a well-defined, pitted scar; only one had two well-defined, round and pitted scars; fifty-one had no scars at all, although they had been vaccinated; the remainder had scars in various forms, shapes and colors; no vaccination had been performed for three months previous to the examination; nevertheless, some of the arms were still crusted. The majority of the older scars contained cicatrices, long, irregular, varying in dimensions from one inch to two inches; some had purple ridges in the centre, some red, others had cavities blue and red with puckering edges. Many of these children were vaccinated sucessfully, showing that, notwithstanding the severe and destructive processes that had previously taken place in the arm, they were not protected. A baby should be vaccinated at four months old, unless it is necessary to do so earlier. Physicians should see the child on the fourth and eighth day after the operation, and satisfy themselves that there is a proper formation of a vaccine vesicle. Vaccinations are constantly seen that are reported to have taken because sores have been generated by the operation which in no way simulate the vaccine vesicle.

It is preferable to vaccinate a child at four months, because this is usually before dentition takes place. In regard to dentition, it is an exceedingly dangerous thing for the physician to teach the mother that any severe attack of illness is due to teething, for she is very apt to delay the physician's attendance on her child that is ill during the dentition period. Dentition, *per se*, is not the cause of any severe attack of illness. The most severe condition due to teething alone is a slight ephemeral fever, a cough or an eruption, not in any way making the child ill enough to require medical attention. Of course, the irritation that is sometimes caused in the gums will make more severe a disease due to some other cause, and the child, during dentition, that is at all affected by this normal process, is more apt to be attacked by the prevailing diseases.

Washing in Cold Weather.

The *Nightingale*, February 14, 1891, says: If your face chaps easily and is uncomfortable in cold weather, try the following: Get a fine quality of Indian meal. Take a handful of this meal and pour boiling water over it. Then add enough cold water to reduce the whole to a bearable temperature. Take into your two hands some of the dry meal, wet this in the water as prepared and scour the face with it, using it upon the hands as you would use the lather of soap. Finally, rinse the face in the specially prepared hot water and dry. Use the towel, sparingly, so that the face may dry partly by evaporation. If afterwards you pass the hand over the face you will be surprised at the smooth comfortable feel which has been given to your irritable skin. You will also find it less sensitive to the wind and cold.

What is accomplished by this process? In the first place the skin is thoroughly cleansed by the handful of uncooked meal, the little particles of which scour out the sebaceous ducts as no amount of soap can do. It is almost impossible to cultivate a crop of black-heads and adhere to this treatment. In the second place the meal over

which the boiling water was poured has been partly cooked so that a soupy consistency is given to the water in which your face is bathed. This dries in a film over the skin, protecting cracks and rendering it much less likely to catch dust. Try this method of taking care of your skin. It is not at the time so enjoyable and does not seem so clean as the old soap and water method, but the results are far superior.

Multiple Herpes Zoster.

In a Clinic Report in the *Medical Chronicle*, February, 1891, Dr. James Mackenzie, of Victoria Hospital, Manchester, says: On account of the rarity of such cases the following appears worth recording.

Mrs. L., aged 51 years, a widow lady in comfortable circumstances, tall and of full habit of body, had been attending four days at a bazaar, when, at times, from over-crowding, the atmosphere was very impure. Previous to this she had been in good health. The second morning, after attendance at the bazaar, she felt intense smarting pain in the right armpit. On looking there she observed a few small blisters. A few hours later a similar pain was felt in the left armpit, and there also a few blisters appeared. During the night and next day there was severe pain shooting down the inner side of both arms, as low as the elbow. Occasionally a feeling of numbness and pain extended down the ulnar half of the left forearm, and to the two inner fingers. Pain also appeared to shoot down the chest, as low as the level of the nipple. There was also pain in the throat and in the nose. Shooting, burning pains were also felt on the inside of the thighs, and small blisters appeared on both thighs and on the nates.

I examined her on October 19, 1889, four days after the beginning of the complaint. In addition to the sensations which she voluntarily described, I found pain and tenderness along the whole spinal column, much aggravated by the slightest pressure on the separate vertebræ. This was worst over the two lowest cervical and upper two dorsal vertebræ. In each armpit there was a large patch of vesicles occupying the hollow of the armpit, about three inches in diameter. On the right side there was a thin irregular streak of papules descending on the side of the chest as low as the level of the nipple. Two days after, these had developed into small vesicles full of clear transparent fluid. On the edge of the posterior fold of the axilla and descending for a few inches towards the inside of the arm was another streak of papules that likewise in a couple of days developed into a crop of vesicles.

On the inner aspect of each thigh, about six inches below the pubes, there was an irregular oval patch of vesicles. The patch on the right thigh measured two inches by one, while that of the left was somewhat smaller. The patches occupied similar positions on each thigh. To the inside of the right fold of the buttock, two inches from the middle line and midway between anus and vagina, was a small irregular red patch, but no papules nor vesicles. She complained of the same peculiar pain here as occurred in the armpit, arm and thigh. She also felt the same pain in the identical spot on the opposite side, but was extremely surprised when I said there was no eruption.

There were also two raw sores about the size of a split pea on either side of the septum of the nose, about an inch from the external opening of the nostril. She said that these had been small blisters, and the pain had been so annoying that she had burst them in the hope of getting relief. The fauces were sore, and looked red in patches, but there were no vesicles.

The illness pursued a very severe and painful course for the next two months. Every few days there would be recurrence of the pain, causing sleepless nights. The situation of the pain was most frequently down the inner half of the left arm, forearm, hand, and two fingers (little and ring fingers). Less frequently and less severely the pain would strike down the same places on the right arm. Occasionally the pain occurred in the face, generally in the cheeks, both at once and on identical places, and also on the inner side of the upper part of the thighs and upper part of the chest. On all those places there developed, after an attack of the pain, an eruption, sometimes limited to one or two papules, some of which developed into vesicles—sometimes a crop of vesicles covering an area the size of a florin, sometimes a streak extending to one or two inches in length.

These attacks gradually diminished in intensity, and she was progressing favorably when, on the 4th of April, 1890, she had a severe attack of pain in the face, followed by an eruption of vesicles situated on both upper eyelids, around both nostrils, and on

both sides of the lower lip. After this attack subsided she had no recurrence of any of the previous severe attacks, but during the next six months, after any occasion when she had any mental bother or worry, she would feel on both cheeks the same peculiar stinging pain, which would continue from five to nine hours and terminate with the eruption of one or two papules. These would either remain stationary for a day or two and disappear, or develop into vesicles. She reckoned there would be at least twelve such attacks, and they ceased exactly twelve months from the onset.

During the attacks of pain affecting the left hand, arm, and, in a less degree, the right also, she complained of the loss of power in her hand and arms, so much so that she felt unable to knit or sew. I could never satisfy myself of any distinct paresis.

Kola Nut of Africa.

Mr. P. L. Simmonds, in the *American Journal of Pharmacy*, December, 1890, gives the following interesting account of the kola nut, which is now attracting so much attention.

This seed or fruit, known under a variety of names in different parts of Africa, as kola, gourou, ombéné, nangoné, kokkorokon and matrassa, has only within a few years come into important notice as a food stimulant. Twenty or thirty years ago, it was incidentally described by Dr. Daniel and Prof. Attfield, in the *Pharmaceutical Journal*, but its extensive employment in Africa was comparatively little known. Although its use as a stimulant, in the place of coffee, tea, maté and coca by other people, had been very general, almost from time immemorial among the various tribes of Equatorial Africa, the product was little known in Europe.

The opening up of Central Africa and the increase of trade on the West Coast has demonstrated its importance as a local article of commerce, and its chemical advantages have become duly appreciated. There are, however, two distinct products; one, the true kola nut, the product of *Sterculia acuminata*, popularly known as the female kola, and the false, or bitter kola, designated as the male kola. The true kola tree grows spontaneously over the range of Western Africa comprised between the 10° of N. latitude to the 5° S. latitude. This tree, to which attention has of late years been prominently directed by the authorities of Kew, has been introduced from time to time into India, Ceylon, Seychelles, Mauritius and Cochin China in the East; Zanzibar and Sidney, and in French Guiana, British Guiana, Guadaloupe, Dominica and Jamaica in the Western Hemisphere.

Incidental mention of this nut has been already made in this Journal—1880, pp. 6 and 7; 1883, p. 27; 1884, p. 166, and 1886, p. 391. The tree commences to bear at 4 or 5 years, but it is not until 10 years that it is in full fruit, when it will produce on the average 120 pounds of seed twice yearly. Flowering in June, the pods will ripen in October and November, and a second crop will be yielded in May and June following, The fruits as they ripen have a yellowish-brown color, and, as the central suture opens, exposes both red and white seeds. The women remove the seeds, which are most appreciated and valued when they are fresh and moist. To preserve them, they are placed in baskets, in layers, with the leaves of *Sterculia cordifolia*, which are kept damp. If they are kept, or to be transported any distance, the nuts are washed and fresh moistened leaves added every month. The packages, weighing about 1 cwt., are sent to the Gambia, Gone and other districts. When the nuts become dry, they are reduced to powder, and taken in this state by the caravans to the interior. They frequently arrive, however, in a fresh state at Sokoto and Kouka, in the Soudan, and at Timbuctoo.

Not only are the kola nuts consumed in Africa, but they are also exported to Brazil for the use of the negroes there. The seeds of *Sterculia Chica* and *S. lasiantha* are also eaten in Brazil.

Sierra Leone is the principal market for these nuts. Ten years ago, about 750,000 pounds of kola nuts were imported there, and 600,000 pounds to the Gambia.

The unerring instinct of man, even in uncivilized countries, has led him to select, from the many thousands of plants presented to him in Nature, just four or five, which, from their alkaloid active principle, theine, seem to be a necessary rather than a luxury of life. These nuts contain more theine (viz., 2.34) than most of the other dietetic products in use. The properties of the nut are said to be two-fold. In the first place, it enhances to many palates the flavor of food eaten afterwards; secondly, it possesses the

more important function of staying the cravings of hunger, and enabling those indulging in it to endure prolonged labor without fatigue. Being bitter, they are used as a stomachic and a tonic.

It is beneficial in periodical and chronic headaches, in heart complaints and diarrhœa; and, mixed with cocoa, it has been found a sustaining and stimulating adjunct in exhaustive and wasting diseases. It is said to clarify beer and spirits, and, like the clearing nut (*Strychnos potatorum*), to render drinkable foul water. It is even spoken of as a cure for drunkenness, from the amount of theine it contains. Probably other species of kola or sterculia may furnish seeds equally used if they contain caffeine.

The false kola nut has been named *Garcinia Kola* by Dr. Heckel, but is not yet well defined, although it resembles the Eastern *Garcinia Morella*. These seeds are employed like the true kola nuts, although they have not the same properties, being destitute of the alkaloid. They are contained in a large berry, like an apple, to the number of three or four; oval, cuneiform. They are chewed generally on the West Coast, and have a bitter flavor, like green coffee. They are said to be an effectual remedy for cold in the head, a few seeds being chewed in the course of the day.

Contagious Diseases Act.

The effect of the Contagious Diseases Act in England has been a subject of much discussion at different times. The latest on the subject is in the *Lancet*, February 14, 1891, where it is stated that, for the purposes of comparing stations under the Acts with those not under them, fourteen of the latter were selected by Surgeon-General Lawson, in a recent paper, for comparison, and were called "fourteen stations never under the Acts." Besides these two sets of stations was a third, designated "all the stations never under the Acts." In 1860, at the fourteen stations which came under the Acts in 1864 and subsequently, the ratio of primary sores was 146; at the fourteen unsubjected stations 134, and at all the stations never under the Acts 131. From these points all fell, so that in 1862 they stood at 117, 103 and 99 respectively. In 1863 the admissions at the fourteen unsubjected stations rose to 117, while those at the fourteen subjected were 107, and all the unsubjected 108. The compulsory examination began to take effect in 1867, and though there was an increase of the incidence of the disease on the country as indicated by rises in the ratio of 17 per 1,000 in both the fourteen and whole unsubjected districts, that at the fourteen stations under the Acts was 4 per 1,000 only; and from this year the ratios at the fourteen subjected stations were always much under those in the whole until 1884, the last year of the comparison. In 1871 the incidence of the disease on the country seemed at its lowest, being 93 for the fourteen unsubjected stations, 81 for all the subjected and 51 only for the fourteen subjected. The stoppage of pay showed its effects in 1874 by a fall at each class of stations, which was continued in 1875, and still traceable up to 1877, after which the advance of another epidemic wave caused a rise at the fourteen unsubjected stations of 40 per 1,000, at all the unsubjected of 20, while at the fourteen subjected it was 4 only. In 1879 there was a slight reduction of the ratio at both classes of unsubjected stations, but a rise of about the same amount at the fourteen subjected; but in 1880, with the cessation of stoppage of pay, there was a general rise, amounting to 39 at the fourteen unsubjected stations, to 37 on the whole unsubjected and to 27 at the fourteen subjected stations; a portion of this was no doubt due to an increasing incidence of the disease over the country, but a large portion also to the removal of the inducement to conceal primary forms of the disease by stoppage of pay. The beneficial effects of the Acts will be seen by the following figures. In 1860 to 1863, when no Acts were in force, the ratio of primary sores at the stations subsequently protected by them was 129.8. In 1870 to 1873, the Acts being then enforced in all, it fell to 52.5. Secondary syphilis fell from 39.9 to 20.2; gonorrhœa from 134.6 to 100.3. At all the stations never under the Acts the fall in primary sores was from 116.3 to 86.0, in secondary disease from 30.5 to 27.4 and in gonorrhœa from 116.1 to 95. At the fourteen unsubjected stations primary sores fell from 120.6 to 107.9; secondary syphilis rose from 31.6 to 31.8; gonorrhœa fell from 112.1 to 71.6. In 1880 to 1882, stoppage of pay having terminated, the ratio of primary sores at the protected stations was 75.6, secondary syphilis 26.6, gonorrhœa 99.0. At all the stations never under the Acts the ratio of primary sores was 123.0; that of secondary

syphilis 32.5; gonorrhœa 110.4. At the fourteen unsubjected stations the ratio of primary disease was 175.9, of secondary syphilis 38.9 and of gonorrhœa 128.4.

The Acts were suspended in 1883, and wholly repealed subsequently; the separation of the tables has not been continued since 1884. The ratios of disease among all the troops are as follows:

	Primary Sores.	Secondary Syphilis.	Gonorrhœa.
In 1860, ratio per 1,000 of admission	140	36	133
In 1885, ratio per 1,000 of admission	127	27	121

From this it will be seen that the ratio of disease has returned to what it was in 1860 before the first Act was enforced.

There are many other interesting points in Inspector-General Lawson's paper which show immense pains, great research and a most thorough knowledge of the whole subject. Enough, the *Lancet* says, has been given to show the benefits of the Contagious Diseases Acts and the disastrous results of their repeal.

Cotton and Collodion Dressing for the Chest.

In the *Annals of Gynecology and Pediatics*, February, 1891, there is a letter from Dr. William Hunt, of Philadelphia, on a new method of dressing the chest in pneumonia, pleurisy, pleurodynia, etc. Dr. Hunt says:

This is the method I advise to dress the chest in a case of pneumonia, pleurisy and pleurodynia. Do it on a large scale, in the same way that we now dress abrasions and bruises. If there is to be any cupping or other preliminary operation, have that attended to; then all the ingredients wanting are pure collodion and absorbent cotton in smooth layers, and a good broad brush, like mucilage brushes. Apply a very thin layer over the side affected from spinal column to sternum, and secure it with collodion smeared thoroughly over it. Then go on with thicker layers, securing them with collodion until a good padding is obtained, paying particular attention to the edges. In double cases you can act accordingly. The advantages are:

1. The one dressing, if well applied, will last throughout the case, and so

2. The fatigue and discomfort of frequent poulticing are avoided.

3. The side, in single cases, is held as in a splint, while the free side does the breathing. A first-class non-conductor is covering the chest. I am not sure but that the contracting collodion may have some influence in controlling the blood supply.

4. There is no particular interference, in one who has a good ear, with physical examination. Maybe it would be a good thing if there was; for, having once made the diagnosis, what is the use of exhausting the patient every day by trying to find out whether one-eighth of an inch, more or less, is involved? The general symptoms will tell that.

Calomel and Salt.

The *Western Druggist*, February, 1891, says: Calomel and salt are by many believed to be incompatible on account of the alleged formation of mercuric chloride. This theory has often been contradicted, but Paul Adam has conducted a fresh series of experiments, the results of which he has recently reported. He boiled together calomel and salt in open and in closed vessels, in the presence of gastric juice, and the extract of beef. He also experimented with animals. His conclusions are: Boiled together in open vessels with the alkaline (especially ammonium) chlorides, calomel yields mercuric chloride. Under exclusion of the atmosphere, however, even in the presence of organic matter, no corrosive sublimate is formed. Hence there is no danger in the administration of these two agents together.

Study of Medicine in Thibet.

The *British Medical and Surgical Journal*, February 5, 1891, says: The Buddhist Lamas' University, in the Transbaikal Province of Thibet, has a medical course of ten years. According to *Nature*, a traveler named Ptitsyn has returned from that country with a collection of medical books and drugs illustrative of the knowledge and the methods of practice in Thibet. Mr. Ptitsyn remarks that he has found over one hundred diseases described in the Buddhist literature, and of these a mythical origin is ascribed to only two. Strictly medical subjects are not studied until the fifth year of the course, the first four years being devoted to the study of the languages and theology. The eighth year is devoted to astrology, and philosophy is studied in the last two years.

THE

MEDICAL AND SURGICAL REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M. D.,

EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,

P. O. Box 843. Philadelphia, Pa.

☞SUGGESTIONS TO SUBSCRIBERS:

See that your address-label gives the date to which your subscription is paid.

In requesting a change of address, give the old address as well as the new one.

If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:

Write in ink.

Write on one side of paper only.

Write on paper of the size usually used for letters.

Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."

Make communications as short as possible.

NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.

When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.

The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

PELVIC INFLAMMATION AND THE GENERAL PRACTITIONER.
